PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. Volume 7 appeared in, and was dated 1973. There was no hiatus in literature coverage from Volume 6 which was dated 1971. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism, and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

SUBJECT INDEX		

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

yr	year(s)

NOTE

Due to circumstances beyond our control, *Gastroenterology Abstracts and Citations*, Volume 7, Number 4, April 1973 inadvertently was mailed to another mailing list. We have arranged for additional copies to be printed and mailed to the *Gastroenterology Abstracts and Citations* mailing list. This should occur in the very near future.

We regret this inconvenience to our readers, and this office will continue surveillance to make sure that this issue will be mailed out correctly as soon as possible.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

0001 SEPARATION OF LIPASE-POSITIVE CELLS FROM SUSPENSIONS OF PANCREAS CELLS IN AN ISOKINETIC GRADIENT OF FICOLL IN TISSUE CULTURE MEDIUM.

(E.) Blackmon, J.; Pitts, A.; Pretlow, II, T.G. (Dept. Pathol., Univ. Alabama, Birmingham). *Am. J. Pathol.* 72(3):417-426, 1973.

Lipase-positive cells were separated from suspensions of hamster pancreas cells both by velocity sedimentation and isopycnic sedimentation in polysucrose gradients. Lipase-positive cells were 51.0% of the disaggregated pancreas cells in the starting sample suspension. The purest gradient fractions from experiments using velocity sedimentation for cell separation contained a mean of 98.8% lipase-positive cells. Cell separation using isopycnic centrifugation was less effective than cell separation using velocity sedimentation and resulted in a mean purity of only 89.8% lipase-positive cells. Lipase positivity was assessed using the Gomori technique with the conditions for fixation slightly modified to be suitable for disaggregated cells. The current method used for purification of pancreatic exocrine cells should be useful for studying protein synthesis and differentiation *in vitro* in a single kind of cell independent of the other cell types, unknown hormonal stimuli, nutritional variations, and nervous stimuli which are present *in vivo*.

0002 THE INFLUENCE OF TRIIODOTHYRONINE AND RIBOFLAVIN DEFICIENCY ON THE RAT LIVER WITH SPECIAL REFERENCE TO MITOCHONDRIA. A MORPHOLOGIC, MORPHOMETRIC, AND CYTOCHEMICAL STUDY BY ELECTRON MICROSCOPY.

(E.) Reith, A. (Norwegian Radium Hosp., Oslo). *Lab. Invest.* 29(2):216-228, 1973.

Morphometric and cytochemical methods were used to study the fine structure of the rat liver during thyroid hormone influence (25 μg/100 g) and riboflavin deficiency for 83 days. Thyroid hormone caused a decrease in the number of mitochondria, the volume fraction of smooth endoplasmic reticulum and glycogen, and the average size of a hepatocyte. Increases occurred . the surface of the cristae membranes, the number of microbodies, and the volume and surface of the outer and cristae membrane of the average mitochondrion. Riboflavin deficiency caused a decrease in the mitochondrial fractional volume and the surface of the cristae membranes; and an increase in the average size of a hepatocyte and the fractional volume of microbodies, the smooth endoplasmic reticulum, and the glycogen. Thyroid hormone administered during riboflavin deficiency caused marked biogenesis of mitochondria in terms of an increase of their number, their fractional volume, and the surface area of their outer and inner boundary membranes and cristae membranes. This state was also characterized by remarkable mitochondrial forms: mitochondria with transverse partitions, mitochondria with elongated cristae forming membrane stacks which displayed cytochrome oxidase activity, and a larger number of cupshaped and dumbbell-shaped organelles. The last mentioned forms were interpreted as a cytologic indication of mitochondrial biogenesis.

0003 ACINAR CELL PROLIFERATION IN THE RAT PANCREAS DURING EARLY POSTNATAL GROWTH.

(E.) Sesso, A.; Abrahamsohn, P. A.; Tsanaclis, A. (Biomed. Inst., Univ. Sao Paulo, Brazil). *Acta Physiol. Lat. Am.* 23(1):37-50, 1973.

During days 2 to 20-23 of postnatal life the mitotic and labeling indices of the pancreatic acinar cells in white Wistar rats are distinctively higher than those observed by the 30th day and onward. The evolution of these indices and of the total pancreatic DNA suggested that during the initial postnatal period the acinar cells might be expanding in number exponentially. Ultrastructural analysis indicated that all the mitotic cells in the acini are fully differentiated zymogenic cells. Repeated thymidine-^3H injections to suckling rats showed that at least 90% of the acinar cells derive from division of preexisting differentiated cells. Estimation of the acinar cell cycle parameters showed that the generation time T, G_1, S, G_2 and mitosis last 111 hr, 97 hr, 9.5 hr, 2.8 hr and 1.3 hr, resp. Significant cytophysiological changes occur in the acinar cell coincidental with the period of high mitotic activity. The amount of cytoplasmic RNA is low during the initial 2 postnatal weeks; it then rises rapidly until the 30-40th day when adult levels are reached. The ability to incorporate tritiated amino acids into migratory proteins also rises continuously from day 2 until the end of the 1st month post partum. Thus, it is apparent that the highest level of mitotic activity occurs in differentiated cells which have not yet attained full maturity.

0004 METABOLICALLY ACTIVE, SINGLE CELL PREPARATIONS FROM THE MUCOSAL EPITHELIUM OF RABBIT SMALL INTESTINE.

(E.) Padron, J.; Gallagher, J. T.; Kent, P. W. (Dept. Biochem., Univ. Oxford, England). *Br. J. Exp. Pathol.* 54(4):347-351, 1973.

Limited treatment with papain has liberated isolated epithelial cells from the epithelial mucosa of the rabbit small intestine. Such cell populations retain their brush borders, have a Q_{O_2} of -10 μl O_2/mg protein/hr and incorporate D[^{14}C]glucosamine into 3 high molecular weight components having certain electrophoretic properties characteristic of glycoproteins. The pattern of radioactive labeling in these 3 macromolecules suggests that the slowest moving electrophoretic component, which contained the highest level of radioactivity, may be a precursor of one of the faster moving components. The results of this study demonstrate the efficacy of the limited papain method of digestion for preparing metabolically active cells from rabbit intestinal epithelium capable of maintaining the biosynthesis of glycoproteins. This system should be valuable for studying glycoprotein metabolism in epithelial cells without interference from sub-epithelial tissues, and in evaluation pharmacologically active agents for their therapeutic value.

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

0005 MORPHOLOGY AND DISACCHARIDASE LEVELS OF JEJUNAL BIOPSY SPECIMENTS FROM HEALTHY BRITISH SUBJECTS. *(E.)* Pena, A. S.; Truelove, S. C.; Whitehead, R. (Gastroenterol. Dept., Ziekenhuis, Leiden, Netherlands). *Digestion* 8(4):317-323, 1973.

The morphological features of jejunal biopsy specimens from 21 healthy British volunteers were studied. In addition to finger-like villi, a feature in every case, and narrow leaf-shaped villi, present in 14 cases, 3 biopsies showed broad leaves and/or short ridges. Quantitative histological methods provided a yardstick with which to compare one specimen with another. Such measurements are of obvious use in determining whether a given biopsy specimen falls in a normal morphological range. Disaccharidase activity was also estimated and the mean values for lactase, sucrase, and maltase were, resp., 4.8, 7.9, and 22.4 U/g wet weight of tissue. Two subjects gave definite evidence of hypolactasia.

0006 THE CELL CYCLE TIME IN THE FLAT (AVILLOUS) MUCOSA OF THE HUMAN SMALL INTESTINE. *(E.)* Wright, N.; Watson, A.; Morley, A.; Appleton, D.; Marks, J.; Douglas, A. (Dept. Pathol., Univ. Newcastle upon Tyne, England). *Gut* 14(8):603-606, 1973.

A hyperproductive mucosal state in gluten-sensitive enteropathy has been proposed on the basis of an elevated mitotic index, but this parameter depends on the mitotic duration when used as an index of proliferative status. The mitotic duration was therefore measured in 2 control patients with normal villous mucosae (a 61-yr-old man with diagnosis of rosacea and leg ulceration resulting from stasis and another 61-yr-old man with diarrhea) and in 2 patients with the flat avillous mucosa of untreated gluten-sensitive enteropathy (a 37-yr-old man with dermatitis herpetiformis and megaloblastic anemia due to folic acid deficiency, and a woman aged 55 yr with untreated celiac disease). Two different stathmokinetic techniques with vincristine were used. No significant difference in mitotic duration was found, but values obtained for cell cycle time showed a halving in the flat mucosae. An increased rate of cell production in the small bowel mucosa of untreated gluten-sensitive enteropathy is thus confirmed.

0007 HORMONAL CONTROL OF PANCREATIC GROWTH. *(E.)* Mainz, D. L.; Black, O.; Webster, P. D. (VA Hosp., Augusta, Ga.). *J. Clin. Invest.* 52(9):2300-2304, 1973.

The effects of chronic administration of bethanechol and cholecystokinin-pancreozymin (CCK-PZ) on the pancreas were studied. Male albino rats were given saline, bethanechol, (6 mg/kg), or CCK-PZ (20 U/kg) i.p. twice daily for 5 days. Bethanechol administration caused a 20% increase in pancreatic weight and a 33% increase in mg protein/100 µg DNA. In bethanechol-treated groups, amounts of DNA/g body weight and incorporation of [^{14}C]thymidine into DNA were similar to controls. CCK-PZ administration caused a 71% increase in pancreatic weight and a 38% increase in mg protein/100 µg DNA. In CCK-PZ-treated groups, amounts of DNA/g increased 42% and [^{14}C]thymidine incorporation into DNA increased 185%. Thus, bethanechol administration was associated with increases in pancreatic cell mass (hypertrophy). CCK-PZ was associated with increases in cell mass and cell numbers (hypertrophy and hyperplasia). This information suggests that CCK-PZ is important in maintaining pancreatic functional integrity. Although bethanechol and CCK-PZ elicit similar secretory responses, their mode of action on the cell appears to be different at least as far as growth influences are concerned.

0008 THE GOLGI COMPLEX. I. ISOLATION AND ULTRASTRUCTURE IN NORMAL RAT LIVER. *(E.)* Sturgess, J. M.; Katona, E.; Moscarello, M. A. (Hosp. Sick Children, Toronto, Canada). *J. Membr. Biol.* 12(4):367-384, 1973.

The ultrastructural arrangement of membranes of the Golgi complex was characterized in Golgi fractions isolated from the livers of male Wistar rats. A modified method for isolation of these fractions provided a good yield of Golgi membranes (60 to 70%) is obtained with greater than 50-fold purification of sialyl transferase, an enzyme specific for the Golgi complex. The isolated membranes appear well preserved, and both the dimensions and appearance of the Golgi complex observed by negative staining and in sections of the isolated membranes correlate well with that in liver sections. The Golgi complex comprises a series of plate-like structures, each consisting of a central sac or cisterna surrounded by a network of fine tubules. The tubules increase in diameter toward the periphery of the plate and are associated with the formation of vacuoles or secretory vesicles. Indirect evidence has indicated that these tubules are the site of glycoprotein biosynthesis, and it seems likely that macromolecular carbohydrate materials pass through them. The manner in which the structure of the Golgi complex is related to its role in glycoprotein biosynthesis is under study.

0009 SCANNING ELECTRON MICROSCOPY OF RAT'S LIVER. APPLICATION OF FREEZE-FRACTURE AND FREEZE-DRYING TECHNIQUES. *(E.)* Brooks, S. E. H.; Haggis, G. H. (Dept. Pathol., Univ. West Indies, Kingston, Jamaica). *Lab. Invest.* 29(1):60-64, 1973.

Portal vein perfusion of the liver of male Sprague-Dawley rats was carried out with Ringer's solution followed by 2.5% glutaraldehyde. Liver samples were postfixed in osmium tetroxide, washed in distilled water, snapfrozen in Freon-12, and fractured at -150 C. After freeze-drying at -80 C., a thin layer of carbon and gold was applied under vacuum. Sinusoidal fenestrations and the relation of the endothelial cells to hepatocyte microvilli and reticulin fibers were delineated using the scanning electron microscope. Images of bile canaliculi and adjoining plasma membranes were obtained. These techniques have great potential for the study of a variety of liver diseases, particularly because large areas of the linings can be examined and areas showing pathologic change might be detected which would not be observed by other forms of microscopy.

0010 THE RESPONSE OF SMOOTH MUSCLE CELLS IN THE RABBIT COLON TO ANAL STENOSIS: A PRELIMINARY REPORT. *(E.)* Brent, L. (Roy. Children's Hosp., Melbourne, Australia). *Pathology* 5(3):209-218, 1973.

The morphological responses of smooth muscle cells in the colon to different degrees of anal stenosis, and the cell changes subsequent to release of that obstruction were studied in growing and adult rabbits. The colon reacted first by dilatation then by thickening of the wall. Microscopically apparent were disruption of the muscle layers, cellular hypertrophy, increased connective tissue, and mitosis of smooth muscle cells. The sequence of cellular hypertrophy was -cytoplasmic enlargement, nuclear enlargement, mitosis, and cellular hyperplasia. Quantitation revealed that cellular hypertrophy up to 3 times the normal value occurred in proportion to the duration and degree of obstruction. In the adult animal, the muscular thickening was due mainly to hypertrophy with only a 20-30% increase in cell population. In the growing rabbit, hyperplasia and hypertrophy contributed equally to the total muscular thickening. Cell and nuclear size slowly decreased upon release of obstruction, but the increased cell numbers remained.

0011 PANCREATIC AND HEPATIC ULTRASTRUCTURE IN OFFSPRING OF RABBITS WITH PROTEIN MALNUTRITION. *(E.)* Wellmann, K. F.; Adachi, M.; Volk, B. W. (Kingsbrook Jewish Med. Ctr., Brooklyn, N.Y.). *Virchows. Arch* [*Pathol. Anat.*] 360(4):327-337, 1973.

Pregnant New Zealand rabbits (10) were fed a low-protein, low-fat, high-carbohydrate diet during the second half of gestation and during the subsequent period of lactation. Baby rabbits (31) born to these protein-restricted does and suckled by them for 2 or more weeks showed loss of fur, stunted growth, fatty metamorphosis, and increased glycogen storage in the liver, and atrophy of pancreatic acinar cells associated with loss of zymogen granules as well as widespread cytoplasmic vacuolization. It is likely that these changes are not merely the effect of caloric restriction but also reflect a more specific nutritional deficiency (protein deficiency).transmitted by the mother rabbit to her offspring. Occasionally lipid globules in hepatocytes were manifest before pancreatic acinar cell alterations. This suggests that hepatic lesions in protein malnutrition result directly from the deficient diet and are not secondary to pancreatic changes.

0012 REGENERATION OF THE INTESTINAL MUCOSA AFTER SELECTIVE NECROSIS: FUNCTIONAL, MORPHOLOGICAL, AND MICROCIRCULATORY STUDY. *(Fr.)* Mirkovitch, V.; Robinson, J. W. L.; Fischer, A.; Winistorfer, B. (Cantonal Hosp., Lausanne, Switzerland). *Helv. Chir. Acta* 40(1/2):291-294, 1973.

Intestinal necrosis was selectively induced in the mucosa of male and female dogs by introducing 6 to 20 ml of a 10% formaldehyde solution into the lumen of a loop of small intestine and draining it out 10 min later. The muscularis propria remained intact, but active transport ceased. An inflammatory reaction appeared in the submucosa during the first 24 hr when mucosal circulation stopped. After 1 week the acellular remnants of mucosal phantoms were partially covered with granulation tissue. Regenerative proliferation began during the 2nd week with a unicellular layer, but villi appeared again only at the end of 4 weeks. The final structure of regenerated mucosa differed from that in intestinal loops of untreated controls. Formaldehyde-treated intestinal loops were shorter and covered with pale mucosa. Loops which lost more than 40% of their original length became stenotic, and no mucosal regeneration occurred over the surface treated with formaldehyde. Histologically, the villi in this regenerated mucosa were shorter, thicker, and irregular in shape. Despite pronounced inflammation, microcirculation was good and active transport was normal. No explanation can be offered for the appearance of isolated groups of enterocytes during the 3rd week or for shortening and stenosis of the intestinal loops.

0013 ULTRASTRUCTURE, CYTOCHEMISTRY, AND BIOGENESIS OF GASTROINTESTINAL MUCINS. *(Fr.)* Thiery, J. P. (Res. Ctr., Ivry, France). *Ann. Anat. Pathol. (Paris)* 17(3):307-326, 1972.

0014 MORPHOMETRIC STUDIES BY MEANS OF AUTOMATIC ANALYSIS OF MICROPHOTOGRAPHS OF MURINE LIVERS FOLLOWING OESTRASTILBEN APPLICATION. *(Ger.)* Simon, H.; Arnold, F.; Kemmer, C.; Kunze, K. D.; Meyer, W.; Recknagel, R.; Wagner, H. (C. G. Carus Acad. Med., Dresden, Germany). *Exp. Pathol.* 8:48-57, 1973.

0015 REVISED WIESBADEN CLASSIFICATION OF GUT ENDOCRINE CELLS. *(E.)* Solcia, E.; Pearse, A. G. E.; Grube, D.; Kobayashi, S.; Bussolati, G.; Creutzfeldt, W.; Gepts, W. (Diag. Inst. Pathol. Univ. Pavia, Italy). *Rend. Gastroenterol.* 5(1):13-61, 1973.

ABSORPTION—EXCRETION—TRANSPORT

0030 THE EFFECT OF CONJUGATED AND UNCONJUGATED BILE ACIDS ON WATER AND ELECTROLYTE ABSORPTION IN THE HUMAN JEJUNUM. *(E.)* Russell, R. I.; Allan, J. G.; Gerskowitch, V. P.; Cochran, K. M. (Roy. Infirm., Glasgow, Scotland). *Clin. Sci. Mol. Med.* 45(3):301-311, 1973.

A perfusion system employing a proximal occluding balloon was used to study the effect of conjugated and unconjugated bile acids in various concentrations on the absorption of water, sodium, and chloride in the proximal jejunum in man. Unconjugated cholic acid and its glycine and taurine conjugates

had no significant effect on water and electrolyte absorption. Water and electrolyte absorption were significantly inhibited by unconjugated deoxycholic acid (3 mM) and net secretion occurred at concentrations of 5, 7, and 10 mM. When taurodeoxycholic and glycodeoxycholic acid solutions were used, similar results were obtained. A greater effect was noted with higher concentrations of bile acids. Unconjugated chenodeoxycholic acid caused net water and electrolyte secretion at 3 mM concentration. This effect was more marked with higher concentrations of bile acid. Taurochenodeoxycholic acid (3 mM) also caused inhibition of absorption, and net secretion occurred at a concentration of 10 mM. The results show that dihydroxy bile acids, conjugated or unconjugated, inhibit water and electrolyte absorption in the proximal jejunum in low concentration and cause net secretion in high concentration.

0031 REGULATION OF CHOLESTEROL METABOLISM IN THE DOG. II. EFFECTS OF COMPLETE BILE DIVERSION AND OF CHOLESTEROL FEEDING ON POOL SIZES OF TISSUE CHOLESTEROL MEASURED AT AUTOPSY.

(E.) Pertsemlidis, D.; Kirchman, E. H.; Ahrens, Jr., E. H. (Mt. Sinai Sch. Med., New York, N.Y.). *J. Clin. Invest.* 52(9):2368-2378, 1973.

The effects of high-cholesterol diets or bile diversion on the sizes of body cholesterol pools were studied at autopsy in 6 adult pedigreed dogs. Total body cholesterol was determined by measuring the cholesterol content of discrete organs and of the eviscerated carcass. Neither cholesterol feeding nor bile diversion altered total body cholesterol or the cholesterol content of individual organs and tissues. Thus, high-cholesterol feeding did not lead to substantial expansion of tissue cholesterol pools. When estimated from isotopic data, the total amount of exchangeable cholesterol in animals with an intact enterohepatic circulation was essentially the same as that measured chemically. Apparently there was little or no nonexchangeable cholesterol in these dogs, except in skin and nervous tissue, regardless of the cholesterol content of the diet. This correspondence of estimates was not obtained in the bile-diverted dogs. It is suggested that the accelerated rate of cholesterol synthesis in these animals caused the defect in the isotopic estimates. Gross and microscopic morphology of all organs and tissues was examined. Abnormal findings were limited to the biliary tract and the urinary collecting system of the 2 bile-diverted dogs. Multiple bilirubinate gallstones were found, and mild pyelitis and ureteritis were present on the side of the bilio-renal shunt, but the urinary bladder was normal. Histologic evidence of moderate degree of cholangitis was found in 1 of the 2 bile-shunted dogs, but in neither dog was there evidence of impedance of bile flow.

0032 EFFECT OF FENFLURAMINE ON THE INTESTINAL ABSORPTION OF TRIGLYCERIDES.

(E.) Bizzi, A.; Veneroni, E.; Garattini, S. (Inst. Pharmacol. Res., Milan, Italy). *Eur. J. Pharmacol.* 23(2):131-136, 1973.

Fenfluramine (20 mg/kg, i.p.) markedly decreased plasma triglycerides in fed male Sprague-Dawley rats but not in fasted rats. When this compound was administered to rats in a post-absorptive state, a diminution in lymphatic flow and in triglyceride concentration was observed. Moreover, pretreatment with fenfluramine inhibited a rise in plasma and lymph triglycerides, normally found after an olive oil load (20 mg/kg). No alterations were noted in the flow rate and density of bile. The motility of the small intestine was considerably decreased. In fed rats receiving fenfluramine, no change was observed in plasma cholesterol and phospholipids. These data suggest that the lowering of plasma triglycerides, elicited by fenfluramine, is at least partially due to inhibition of the intestinal absorption of triglycerides.

0033 REGULATION OF CHOLESTEROL METABOLISM IN THE DOG. I. EFFECTS OF COMPLETE BILE DIVERSION AND OF CHOLESTEROL FEEDING ON ABSORPTION, SYNTHESIS, ACCUMULATION, AND EXCRETION RATES MEASURED DURING LIFE.

(E.) Pertsemlidis, D.; Kirchman, E. H.; Ahrens, Jr., E. H. (Mt. Sinai Sch. Med., New York, N.Y.). *J. Clin. Invest.* 52(9):2353-2367, 1973.

A 3-yr study of 6 adult pedigreed dogs was conducted to determine the effects of cholesterol feeding and bile diversion on cholesterol absorption, synthesis, and storage. These measurements were based on cholesterol balance and isotope kinetic studies. In the 6 dogs with undisturbed enterohepatic circulations fed a "cholesterol-free" diet, the rate of cholesterol synthesis ranged from 225-508 mg/day. In 2 dogs studied subsequently on cholesterol-containing diets, absorption of cholesterol was 71-94% on a dietary intake of 0.5 g/day; on high cholesterol intakes (2.7-3.0 g/day) the rate of absorption dropped to 43-51% of daily intake, but the absolute amounts absorbed increased. Cholesterol feeding caused accelerated bile acid formation and excretion, as well as nearly total inhibition of cholesterol synthesis. These 2 compensatory mechanisms were sufficient to maintain zero balance of cholesterol when cholesterol intake was higher. Plasma cholesterol concentrations in the 2 dogs increased 37 and 44%. In 2 other dogs bile was completely diverted into the urinary system for nearly 2 yr. When these dogs were put on a cholesterol-free diet, the sum of acidic steroids excreted daily in urine plus neutral steriods excreted in feces was 7 times higher than before surgery. Since these massive excretory losses could not have been sustained by mobilization from tissue cholesterol pools, and since the rate of disappearance of $[4-^{14}C]$cholesterol from the plasma after single i.v. injection was greatly increased after complete biliary diversion, total daily synthesis of cholesterol must have been greatly accelerated, for synthesis was totally unsuppressed. The increased output of fecal neutral steroids could result from transfer of plasma cholesterol across the gut wall or from increased synthesis in the gut. Plasma cholesterol levels were reduced in these 2 dogs by 20 and 27%, and triglycerides decreased by 36 and 43%. Accumulation of cholesterol in body pools in the cholesterol-fed dogs was apparently prevented, according to antemortem measurements. Increased absorption of dietary cholesterol was exactly balanced by suppression of cholesterol synthesis and enhanced bile acid excretion. In the bile-shunted animals antemortem measurements could not predict depletion of tissue stores of cholesterol.

0034 THE CONTRIBUTION OF SOLVENT DRAG TO THE INTESTINAL ABSORPTION OF TRITIATED WATER AND UREA FROM THE JEJUNUM OF THE RAT. *(E.)* Ochsenfahrt, H.; Winne, D. (Pharmacol. Inst., Univ. Tubingen, Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 279(2):133-152, 1973.

Hypotonic, isotonic, and hypertonic buffered solutions containing tritiated water or ^{14}C-labeled urea were perfused through jejunal loops of anesthetized male Wistar rats. The blood flow of the loop was maintained at (0.8-0.9 ml/min/g wet tissue weight). The water net flux was determined using polyethylene glycol as nonabsorbable marker and amounted to ± 30 µl/min/g. A positive water net flux (directed toward the blood) increased the absorption rates (disappearance rate from the intestinal lumen, appearance rate in the intestinal venous blood) of tritiated water and urea by 22 and 41%; a negative water net flux (directed toward the gut lumen) diminished it by 12 and 32%. The data were analysed by a kinetic model with the water net flux as independent variable. The water net flux influenced the absorption of solutes by interacting within the membranes and by changing the volume of blood flowing in the capillaries near the epithelium. This last effect is large for the absorption of the rapidly absorbable tritiated water, but small for the absorption of urea which is 10 times slower. The water net flux in the intestine depended linearly on the osmotic pressure difference between lumen and blood. The hydraulic permeability was 146-180 ml^2/min/g/osm.

0035 INTESTINAL FOLATE ABSORPTION. II. CONVERSION AND RETENTION OF PTEROYLMONOGLUTAMATE BY JEJUNUM. *(E.)* Olinger, E. J.; Bertino, J. R.; Binder, H. J. (Dept. Internal Med., Yale Univ., New Haven, Conn.). *J. Clin. Invest.* 52(9):2138-2145, 1973.

Studies were conducted to determine whether pteroylmonoglutamic acid (PGA) at physiologic concentrations is transported across the small intestine unaltered or is reduced and methylated to the circulating folate form (5-methyltetrahydrofolate [5-MeFH$_4$]) during absorption. [^{3}H]PGA was incubated *in vitro* on the mucosal side of the jejunum in male Sprague-Dawley rats. Of the folate transferred to the serosal side, the percent identified as 5-MeFH$_4$ by DEAE-Sephadex chromatography was inversely related to the initial mucosa PGA concentration: at 7, 20, and 2000 nm, 44%, 34%, and 2%, resp., was converted to 5-MeFH$_4$. However, less than 4% of the folate transferred across ileal mucosa was 5-MeFH$_4$ when the initial mucosa concentration was 20 nM. Specific activity of dihydrofolate (DHF) reductase, the enzyme responsible for converting PGA to tetrahydrofolic acid, was measured in villus homogenates and was significantly greater in the jejunum than in the ileum. PGA conversion to 5-MeFH$_4$ by the jejunum was markedly reduced by 1000 nM methotrexate (MTX), a DHF reductase inhibitor. Studies of transmural flux, initial rate of mucosal entry (influx) and mucosal accumulation (uptake) of folate were also performed. Although MTX did not alter the influx of PGA, MTX decreased jejunal mucosal uptake but increased transmural movement. Transmural folate movement across ileal mucosa was greater than across jejunal mucosa although mucosal uptake was greater in the jejunum than in the ileum. These results could explain the failure of previous studies to identify conversion of PGA to 5-MeFH$_4$ when intestinal preparations were exposed to higher and less physiologic concentrations of PGA. These studies also suggest that 5-MeFH$_4$ may be retained by the jejunal mucosa.

0036 THE INFLUENCE OF BLOOD FLOW ON THE ABSORPTION OF 3-O-METHYLGLUCOSE FROM THE JEJUNUM OF THE RAT. *(E.)* Lichtenstein, B.; Winne, D. (Pharmacol. Inst., Univ. Tubingen, Germany). *Naunyn Schmiedebergs Arch. Pharmakol.* 279(2):153-172, 1973.

Jejunal loops of anesthetized male Wistar rats were perfused (single pass perfusion and recirculation) with buffered solutions containing 3-O-methylglucose in 2 concentrations: below (30 µM) and above (30 mM) blood glucose concentration. The blood flow, the appearance rate in the intestinal venous blood, and the disappearance rate from the intestinal lumen were determined simultaneously, the accumulation in the gut wall at the end of the experiments. The appearance rate and disappearance rate decreased with time at constant intermediate blood flow. A decrease of the blood flow rate from 1.8-0.3 ml/min/g diminished the appearance and disappearance rate. An increase of blood flow from 0.3 to 1.9 ml/min/g caused no increase of absorption; even a slight decrease was observed. A kinetic analysis showed that the different blood flow dependence of 3-O-methylglucose absorption in the experiments with increasing and decreasing blood flow can be explained by a decrease of transport capacity with time, probably due to altered regional blood flow (decreased villous blood flow rate, unchanged total rate). A postischemic inhibition of 3-O-methylglucose absorption was of less importance. The increase in perfusion rate from 0.1 (single pass perfusion) to 10 ml/min (recirculation) increased 3-O-methylglucose absorption and tissue accumulation.

0037 PHENFORMIN-INDUCED ALTERATIONS OF SMALL INTESTINAL FUNCTION AND MITOCHONDRIAL STRUCTURE IN MAN. *(E.)* Arvanitakis, C.; Lorenzsonn, V.; Olsen, W. A. (VA Hosp., Madison, Wis.). *J. Lab. Clin. Med.* 82(2):195-200, 1973.

Jejunal absorption rates of glucose, water, and sodium were measured with a segmental perfusion technique in human volunteers before and 75 min after administration of phenformin (100 mg). Mean glucose absorption was reduced from 4,532 µM/hr/segment to 2,341; water absorption from 228 ml/hr/segment to -25; and sodium absorption from 1,700 µEq/hr/segment to 400. Although mucosal biopsies appeared normal by light microscopy, electron microscopy revealed disappearance of mitochondrial matrix granules in villus absorptive cells after the drug. It is suggested that the diminished rates of active intestinal transport is the consequence of mitochondrial injury with phenformin and an important mechanism of action of the drug in man. The results of these experiments indicate that phenformin substantially reduces the rate at which carbohydrate is absorbed. It is not certain if this decrease benefits the diabetic patient, but it certainly does affect the glucose tolerance test, one of the major criteria of success in management of these patients.

0038 FAT ABSORPTION IN ESSENTIAL FATTY ACID DEFICIENCY: A MODEL EXPERIMENTAL APPROACH TO STUDIES OF THE MECHANISM OF FAT MALABSORPTION OF UNKNOWN ETIOLOGY.

(E.) Clark, S. B.; Ekkers, T. E.; Singh, A.; Balint, J. A.; Holt, P. R.; Rodgers, Jr., J. B. (St. Luke's Hosp., Ctr., New York, N.Y.). *J. Lipid Res.* 14(5):581-588, 1973.

Male Sprague-Dawley rats were given a fat-free diet supplemented with 4% tripalmitin for 8-12 wk from the time of weaning, causing deficiency in essential fatty acids. After feeding 0.5 ml of [^{14}C]triolein or [^{3}H]oleic acid, 72-hr stool recoveries of radioactivity were significantly greater in deficient than in chow-fed rats. The absorptive capacities for triolein or for a medium-chain fat, trioctanoin, measured after 3 and 2 hr of maximal-rate duodenal infusion were not reduced by this deficiency. In everted jejunal slices from essential fatty acid-deficient rats, uptake of micellar [^{14}C]oleic acid at 0-1 C was similar to that of controls. However, the rate of incorporation of fatty acid into triglyceride after rewarming to 37 C was significantly reduced. In essential fatty acid-deficient rats, the specific activities of the microsomal esterifying enzymes acyl coenzyme A (CoA):monoglyceride acyltransferase and fatty acid CoA ligase in jejunal mucosa were 30% lower. However, the total microsomal enzyme activity adjusted to constant weight did not differ significantly in deficient compared with control rats. After intraduodenal perfusion of triolein, accumulation of lipid in the intestinal wall was increased in the deficient rats. Since more than 90% of the absorbed mucosal lipid was present as triglyceride, it is proposed that essential fatty acid deficiency affects the synthesis or release of chylomicron lipid from the intestine. This transport delay was most marked in the midportion of the small intestine.

0039 INTESTINAL TRANSPORT OF TWO DIPEPTIDES CONTAINING THE SAME TWO NEUTRAL AMINO ACIDS IN MAN.

(E.) Silk, D. B. A.; Perrett, D.; Clark, M. L. (St. Bartholomew's Hosp., London, England). *Clin. Sci. Mol. Med.* 45(3):291-299, 1973.

A double lumen perfusion technique has been used to study the absorption of the neutral amino acids glycine and L-alanine from the dipeptides L-alanylglycine and glycyl-L-alanine, and from an equivalent amino acid mixture in man. Glycine was absorbed faster from the dipeptides than from the equivalent amino acid mixture. The difference in absorption rates of glycine and alanine seen when the equimolar mixture of the amino acids was perfused was abolished when either dipeptide was perfused, suggesting that the mechanism of dipeptide uptake by the mucosal cell is independent of the amino acid-transport system. The presence of free amino acids in the lumen during perfusion of both dipeptides suggests that hydrolysis occurs at some stage in the uptake process. Intraluminal hydrolysis was not sufficient to account for the concentration of the amino acids seen. Their presence is perhaps due to hydrolysis of the dipeptides at the brush border. It is suggested that at least 2 modes of peptide absorption occur simultaneously: direct peptide uptake and peptide hydrolysis with subsequent absorption of the released amino acids by the amino acid transport system.

0040 IN VITRO IRON ATTACHMENT TO THE INTESTINAL BRUSH BORDER. EFFECT OF IRON STORES AND OTHER ENVIRONMENTAL FACTORS.

(E.) Kimber, C. L.; Mukherjee, T.; Deller, D. J. (Dept. Med., Univ. Adelaide, Australia). *Am. J. Dig. Dis.* 18(9):781-791, 1973.

Iron attachment to brush border membrane of guinea pig small intestine was measured by an *in vitro* technique. Both inorganic and hemoglobin iron uptake was assessed under various conditions. Electron microscopic and biochemical studies showed that iron was adsorbed to the glycocalyx of the brush border membranes. Dropping the incubation temperature below 37 C caused a progressive reduction in iron attachment. Anaerobic conditions did not significantly affect iron attachment. In iron-deficient animals attachment of both inorganic and hemoglobin iron was increased. Iron attachment was selective depending on the iron stores of the animal. Several iron-binding compounds reduced the uptake of inorganic iron when they were added at the beginning of the incubation period and did not affect attachment of hemoglobin iron. Gastric juice markedly increased attachment of heme iron to the pellet. This effect appeared related to the effect of acid on the hemoglobin molecule.

0041 CONTROL OF CALCIUM ABSORPTION AND INTESTINAL CALCIUM-BINDING PROTEIN SYNTHESIS.

(E.) Bar, A.; Wasserman, R. H. (New York State Vet. Coll., Ithaca). *Biochem. Biophys. Res. Commun.* 54(1):191-196, 1973.

Dihydrotachysterol (DHT; 600 IU i.m. every 3 days), a steroid which does not require 1-hydroxylation for biological activity, was given to day-old White Leghorn cockerels fed a diet which contained no vitamin D$_3$ (30 IU i.m. every 3 days). After 13 days, these 2 groups of chicks were each divided into 3 subgroups which were fed either a control diet (1.05% Ca, 0.75% P), a low-calcium diet (0.1% Ca, 0.75% P), or a low-phosphorus diet (1.05% Ca, 0.36% P). Measurements made on day 23 showed that duodenal ^{47}Ca absorption and the duodenal concentration of calcium-binding protein were significantly higher in vitamin D$_3$-treated chicks fed the low-calcium and low-phosphorus diets than in DHT-treated chicks receiving these diets. DHT-treated chicks were unable to adapt to a low calcium intake, but they did partially adapt to the low-phosphorus diet since ^{47}Ca absorption and calcium-binding protein levels were significantly higher than in the DHT-treated controls. These results are not consistent with the hypothesis that regulation of calcium absorption is mediated by increased synthesis of 1,25-dihydroxycholecalciferol by 1-hydroxylase in the kidney. They indicate an alternate pathway of control.

0042 OBSERVATIONS UPON AMMONIA ABSORPTION FROM THE HUMAN ILEUM. *(E.)* Swales, J. D.; Papadimitriou, M.; Wrong, O. M. (Roy. Infirm., Manchester, England). *Gut* 14(9):697-700, 1973.

Ammonia absorption from the human ileum was observed in a 27-yr-old man with renal failure due to chronic pyelonephritis secondary to a neurogenic bladder which had followed spinal injury. A double ballooned Foley-type catheter was placed so that one balloon was inside the pouch, and the other just outside; the ileal stoma was thus occluded. All solutions contained 1.25 g of polyethylene glycol. To prepare the solution, 0.2 M Tris was titrated to pH 7.0 or pH 8.0 with 0.1 N hydrochloric acid. Ammonium chloride (75 mEq/liter) and hydrazine (400 μg/liter) were added, together with sodium chloride to made the solution isotonic. When isotonic saline was instilled into the ileal sac, the fluid recovered contained insignificant amounts of ammonia (less than 0.5 mEq/liter). The addition of ammonium chloride to the buffered solutions resulted in a slight lowering of pH so that the mean final pH of the two buffered solutions of ammonium chloride was 6.85 and 7.72. The mean absorption of ammonia was 25.0% from the more acid of these solutions and 44.1% from the solution of higher pH. The pH 6.85 solution contained significantly less bicarbonate than the solution buffered at pH 7.72. Significantly more hydrazine was absorbed from the solution buffered at 7.72 than from the solution buffered at 6.85. These results suggest that nonionic diffusion plays an important role in ammonia absorption from the human ileum.

0043 SMALL INTESTINAL PERMEABILITY IN ANIMALS AND MAN. *(E.)* Loehry, C. A.; Kingham, J.; Baker, J. (Roy. Victoria Hosp., Bournemouth, England). *Gut* 14(9):683-688, 1973.

Small intestinal permeability was studied in 12 humans and in albino rabbits. The clearances of urea, uric acid, creatinine, and ^{68}CO vitamin B12 into a segment of duodenum were studied through a triple lumen tube, screened into the 3rd and 4th parts of the duodenum. There is a direct relationship between the levels of urea in the intestinal lumen and the blood. A similar relationship was established for the other substances. Molecular weight varied from 60-80,000. The smaller molecules are cleared at a much faster rate than the larger ones. ^{125}I-labeled polyvinylpyrrolidone (PVP 50 μC) was injected i.v. into 6 patients with no evidence of gastrointestinal disease. Blood was taken 30 minutes after injection and the stools were collected over the next 4 days. Radioactivity increased in the smaller molecular weight fractions in the feces. There is a progressive rise in intestinal clearance with a fall in molecular size. Perfusions of jejunal and ileal segments of rabbits were performed at the rate of 350 ml/hr. The test mixture was composed of 8 g urea, 3 g creatinine, 40 μC of ^{125}I PVP, and 3 μC of ^{57}CO vitamin B12 in 15 ml of normal saline. The perfusate levels of the substances rose concomitantly with an increasing blood level, though the levels in the jejunal segment were always higher than in the ileal. The clearances in jejunum and ileum remained constant over the range of plasma levels studied. The proportionate fall in clearance in all the substances in the ileum remained constant for all the substances with molecular size ranging from 60-40,000. The intestine was perfused in 4-in. segments. With all the substances, there was a fall from the proximal to the distal intestine, the greatest fall occurring in the first 40 in. and then to a lesser extent in the last 40 in. Short 2-in. segments of duodenum and jejunum were cannulated and perfused at a rate of 600 ml/hr. The peak excretion of all the substances was rapidly reached in 1 1/2 to 2 min after injection. Molecular size made no difference to the speed with which the molecules permeated the mucosal barrier.

0044 THE ROLE IN CHYLOMICRON FORMATION OF PHOSPHOLIPASE ACTIVITY OF INTESTINAL GOLGI MEMBRANES. *(E.)* Redgrave, T. G. (Dept. Physiol., Univ. Melbourne, Parkville, Australia). *Aust. J. Exp. Biol. Med. Sci.* 51(4):427-434, 1973.

The role in chylomicron formation of phospholipase activity of intestinal Golgi membranes was studied in female albino rats. Isolated intestinal cells were prepared from rats that had been given 1 ml of 2% cholesterol in corn oil. The prechylomicrons contain significant lipolytic activity toward both phospholipids and triglycerides. The specific activity compared on a protein basis is uniformly higher than similar activities which are present in the whole intestinal cell homogenate. Phospholipase activity shows a broad pH optimum around pH 6 in either cacodylate or piperazine-glycylglycine buffer. Activity decreases markedly above pH 8. Triglyceride lipase activity is maximal at pH 8.0-8.5 in piperazine-glycylglycine buffer. Triglyceride and phospholipid hydrolysis at optimum pH are fairly sensitive to heating and both are severely inhibited by Triton X-100. It is suggested that phospholipase and triglyceride lipase activities are implicated in transport of prechylomicrons out of the intestinal cell.

0045 THE PERMEABILITY OF THE SMALL INTESTINAL MUCOSA: A STUDY USING IRON.

(E.) Loehry, C. A.; Parish, D.; Baker, J. (Roy. Victoria Hosp., Bournemouth, England). *Gut* 14(10):773-777, 1973.

Solutions of ferrous and ferric sulfate (4 g in 15 ml saline), iron sorbitol/ascorbic acid and dextran iron complex were injected into the lumen of the small intestine in albino rabbits and into the mesenteric arterial supply. Sections of the mucosa were stained for ferric ions by immersing for 30 minutes into equal parts of 2% HCl and 2% potassium ferrocyanide (Prussian Blue reaction). Both ferric and ferrous sulfate showed staining as the mucosa is known to convert rapidly the ferrous ion to the ferric form. The ferric ion is bound to various cell structures and its passage through the mucosa could therefore be demonstrated. Iron appeared to pass from the blood into epithelial cells, especially near the tips of the villi, and also between cells as far as the junctional membrane. Studies using ^{59}Fe demonstrated the rapidity of transfer of iron from the blood into the intestinal lumen. After a period of ischaemia epithelial cells in other situations also appeared permeable to iron. Iron sorbitol/ascorbic acid and dextran iron complex did not show staining, presumably because the bound molecule had less affinity for tissue constituents, and also because the mucosa is less permeable to these molecules of larger molecular sizes.

0046 ABSORPTION OF AMINO ACIDS FROM AN AMINO ACID MIXTURE SIMULATING CASEIN AND A TRYPTIC HYDROLYSATE OF CASEIN IN MAN.

(E.) Silk, D. B. A.; Marrs, T. C.; Addison, J. M.; Burston, D.; Clark, M. L.; Matthews, D. M. (Westminster Med. Sch., London, England). *Clin. Sci. Mol. Med.* 45(5): 715-719, 1973.

A double-lumen perfusion technique was used in normal male volunteers to study jejunal absorption of individual amino acids from an amino acid mixture simulating casein and a tryptic hydrolysate of casein consisting of oligopeptides and amino acids. Total absorption was greater from the tryptic hydrolysate (62.4%) than from the amino acid mixture. There was wide variation in the extent to which individual amino acids were absorbed from the amino acid mixture. This was decreased when the tryptic hydrolysate was perfused. Amino acids which were poorly absorbed from the amino acid mixture were absorbed to a substantially greater extent from the tryptic hydrolysate and this was significant for phenylalanine, lysine, glutamic acid, alanine, histidine, and aspartic acid. The results suggest that the characteristics of absorption of amino acid mixtures do not represent those of absorption of the physiological products of intraluminal digestion, oligopeptides and amino acids.

0047 EFFECTS OF CHOLESTYRAMINE, METAMUCIL, AND CELLULOSE ON FECAL BILE SALT EXCRETION IN MAN.

(E.) Stanley, M. M.; Paul, D.; Gacke, D.; Murphy, J. (Abraham Lincoln Sch. Med., Chicago, Ill.). *Gastroenterology* 65(6):889-894, 1973.

Fecal excretion of ^{14}C-cholate was estimated 32 times (16-day studies) in 22 normal subjects. Each subject ate a constant diet (2-day rotation) closely resembling his usual fare. During the third and fourth (4-day) periods, the effects of medications, randomly assigned, administered double blind, in dosages of 15 g per day, were compared with those of methyl cellulose administered during the control period. Methyl cellulose does not increase bile salt excretion but increases the masses of intestinal contents and stools as do the comparison medications. Excretion rates during periods 3 and 4 are compared with the excretion rate during period 2, the control period. Cholestyramine, Metamucil (psyllium hydrophilic mucilloid), cellulose (15 g/day), and cellulose (30 g/day) all increased excretion rates. In direct comparisons in the same subjects cholestyramine increased the excretion rate over 15 g of cellulose. Metamucil and cellulose increase bile salt excretion slightly but significantly; the effect of cholestyramine is several times as great. However, Metamucil and cellulose resemble frequently ingested food components which may be important determinants of "spontaneous" variations in bile salt turnover.

0048 THE HYDROLYSIS OF GLYCINE OLIGOPEPTIDES BY GUINEA-PIG INTESTINAL MUCOSA AND BY ISOLATED BRUSH BORDERS.

(E.) Peters, T. J.; (Roy. Postgraduate Med. Sch., London, England). *Clin. Sci. Mol. Med.* 45(6):803-816, 1973.

The relative rates of hydrolysis of a series of glycine homopeptides by guinea-pig small intestinal mucosa and by isolated brush borders were studied. Oligopeptides up to and including hexaglycine were hydrolysed. No activity was detected against a series of homopolypeptides of molecular weight 10,000-100,000. Except for activity against diglycine, the peptidase activity was greater in the brush-border fraction than in the original homogenate. The relative activity of the peptidase in the brush borders compared to the homogenate increased with increasing length oligopeptide substrate. Analysis of the enzyme reaction products indicated that the brush border contained an exopeptidase. Studies with peptide derivatives containing *N*- and *C*-terminal blocking groups, and with tetraglycine synthesized with either the *N*- or *C*-terminal residues labelled, demonstrated that the brush borders contained an amino-oligopeptidase. Studies with inhibitors and with purified gastric and pancreatic enzymes indicated that this glycine oligopeptidase activity was not due to enzymes from the intestinal lumen which had been adsorbed to the brush borders.

0049 EXTRACTION OF CIRCULATING ENDOGENOUS GASTRIN BY THE SMALL BOWEL.

(E.) Becker, H. D.; Reeder, D. D.; Thompson, J. C. (Univ. Texas Med. Branch, Galveston). *Gastroenterology* 65(6):903-906, 1973.

The concentrations of gastrin was measured by radioimmunoassay in the aorta and the superior mesenteric vein of 8 adult dogs. During the basal period there was no difference between the arterial and venous serum concentration of gastrin. After elevation of the gastrin levels by stimulation of the antrum with 0.1% acetycholine (150 ml/hr), 43% of endogenous gastrin was lost during transit of the small bowel. A threshold level for the uptake of gastrin by the small intestine is suggested. Loss of catabolic mechanisms for gastrin may be responsible, at least in part, for gastric acid hypersecretion seen frequently after massive resection of the small bowel.

0050 INHIBITION OF COLONIC WATER AND ELECTROLYTE ABSORPTION BY FATTY ACIDS IN MAN.

(E.) Ammon, H. V.; Phillips, S. F. (Mayo Clin., Rochester, Minn.). *Gastroenterology* 65(5):744-749, 1973.

The colon of 9 healthy volunteers was perfused with isotonic electrolyte solutions with or without 2 mM concentrations of three C_{18} fatty acids. These were oleic acid, its bacterial by-product 10(9)-hydroxystearic acid, and ricinoleic acid, the active principle of castor oil. Hydroxystearic and ricinoleic acids reduced electolyte and water absorption by more than 50%. These results suggest that C_{18} fatty acids may contribute to diarrhea in states of fat malabsorption by impairing intestinal water absorption. In addition, hydration of dietary fats of hydroxy fatty acids may not be essential for this effect. During perfusion, the three fatty acids were absorbed by the human colon to the same extent.

0051 RELATIONSHIPS BETWEEN ION AND WATER MOVEMENT IN THE HUMAN JEJUNUM, ILEUM AND COLON DURING PERFUSION WITH BILE ACIDS.

(E.) Wingate, D. L.; Krag, E.; Mekhjian, H. S.; Phillips, S. F. (London Hosp. Med. Coll., England *Clin. Sci. Mol. Med.* 45(5):593-606, 1973.

The relationships between ion and water movement in the jejunum, ileum and colon during perfusion with bile acids were studied in 11 healthy volunteers. Perfusion of the human jejunum with low concentrations of glycine-conjugated bile acids in physiological solutions induced net fluid flow that varied between absorption and secretion, with only slight variation of the luminal osmotic and ionic milieu. Regression analysis of the transmucosal net flux rates for water and the principal ions was consistent with the concept of a 'net transported fluid' which was isosmotic with respect to the lumen, with a superimposed fixed net anion exchange unaffected by the rate or direction of bulk flow. Recalculation of earlier data from comparable studies of the human colon showed similar relationships consistent with varying isosmotic bulk flow and fixed ion exchange, the latter differing from that found in the proximal bowel. Studies in the human ileum indicated variable isosmotic bulk flow, but ion exchange was of a lower magnitude than in the jejunum or colon. Qualitatively, ion exchange in the ileum was intermediate between the jejunum and colon. These analyses suggest that transmucosal bulk flow and ion exchange may be quantitatively and spatially independent processes. They provide support for the hypothesis that bulk flow may be intercellular (and hence extracellular), while ion exchange may take place across the luminal face of the mucosal cell.

0052 THE DISTRIBUTION OF ABSORBED ^{3}H-PALMITIC ACID IN THE INTESTINAL VILLI OF THE CAT DURING VARIOUS CIRCULATORY CONDITIONS.

(E.) Jodal, M.; Lundgren, O. (Dept. Physiol. Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 89(3):318-326, 1973.

The distribution of absorbed ^{3}H-palmitic acid within the villous tissue of 20 cats was investigated by determining the amount of radioactivity/unit weight tissue protein in 40-60 μm thick tissue slices cut perpendicular to the long axis of the villi. A bile solution containing the tracer was incubated in the intestinal lumen for 1 min during *in vivo* conditions. At resting blood flow a steep gradient of radioactivity along the villous length was observed, the highest amount of tracer being found at the tip. This gradient was less steep if the experiments were performed during total intestinal ischemia. The tissue content of ^{3}H-palmitic acid could be markedly decreased by intense vasodilatation or by placing a 7% albumin solution on the "luminal" surface of the intestinal epithelial cells, after removing the bile solution containing the tracer. The serum albumin, continuously circulating at the "tissue" surface of the epithelial cells, was far less efficient in lowering tissue content of radioactivity. It is proposed that the results of the present investigation are explained by a trapping of the palmitic acid in the intestinal countercurrent exchanger efficiently hindering net blood absorption of the fatty acid.

0053 AN AUTORADIOGRAPHIC STUDY OF THE INTESTINAL ABSORPTION OF PALMITIC AND OLEIC ACID.

(E.) Haglund, U.; Jodal, M.; Lundgren, O. (Dept. Physiol Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 89(3):306-317, 1973.

The distribution of intraluminally incubated long-chain fatty acids (LFA; ^{3}H-palmitic acid, ^{3}H-oleic acid) within the intestinal villi were studied in 25 cats during *in vivo* conditions with an autoradiographic technique which prevented tracer losses from the tissue. LFA are fairly diffusely localized throughout the whole epithelial cell and, to some extent, also in the lamina propria after 1 or 20 min incubation. Intense vasodilatation or a 7% albumin solution administered intraluminally after the tracer incubation is able to extract a large amount of the absorbed LFA from the epithelial cells. It is suggested that LFA enter the epithelial cells faster than they are re-esterified into triglycerides, resulting in a pool of diffusible LFA within the cells. Although the cells are in close contact with the sub-epithelial capillary network, any subsequent rapid absorption *via* the blood stream does not occur. It is proposed that the hindrance to net blood absorption of the lipid-soluble LFA is a short circuiting of the easily diffusible LFA in the mucosal countercurrent exchanger.

0054 THYROCALCITONIN AND THE JEJUNAL ABSORPTION OF CALCIUM, WATER AND ELECTROLYTES IN NORMAL SUBJECTS. *(E.)* Gray, T. K.; Bieberdorf, F. A.; Fordtran, J. S. (Univ. North Carolina Med. Sch., Chapel Hill). *J. Clin. Invest.* 52(12): 3084-3088, 1973.

Jejunal absorption of calcium, water and electrolytes was measured in 10 normal subjects by the triple-lumen perfusion method. During the control period, water and electrolyte movements were minimal when a bicarbonate-free test solution was infused. By contrast, bicarbonate-containing solutions were readily absorbed in the control period. I.v. infusion of synthetic salmon calcitonin (SCT) (1 Medical Research Council U/kg/wt/hr) over 110-120 min resulted in a marked jejunal secretion of water, sodium, potassium and chloride in 8 of the 10 subjects. This jejunal secretion occurred with both the bicarbonate-free and the bicarbonate-containing test solutions. Calcium absorption was not affected by SCT, and the serum calcium concentration did not fall during SCT infusion. These results suggest that diarrhea in patients with medullary carcinoma of the thyroid may be due to intestinal secretion secondary to high blood concentrations of thyrocalcitonin.

0055 THE ABSORPTION OF THE DIASTEREOISOMERS OF 5-METHYLTETRAHYDROPTEROYLGLUTAMATE IN MAN: A CARRIER-MEDIATED PROCESS. *(E.)* Weir, D. G.; Brown, J. P.; Freedman, D. S.; Scott, J. M. (Sir Patrick Dun's Hosp., Dublin, Ireland). *Clin. Sci. Mol. Med.* 45(5):625-631, 1973.

The human absorption of the diastereoisomers of 5-methyltetrahydropteroylglutamate (5CH$_3$H$_4$PteGlu) was studied. Informed volunteers were injected with 15 mg of PteGlu 24 hr before the test. The test solution (300 μg) ^{3}H-labelled active diastereoisomer), was taken by mouth in 100 ml of water and washed down with a further 200 ml of water. A flushing dose of 15 mg of PteGlu was given parenterally 15 min after the test dose and the urine was collected for 24 hr. A second study was performed during the next 24 hr with the alternate, inactive diastereoisomer. Five normal subjects with no gastrointestinal, hematological, or urinary disease and 4 adult untreated celiac patients were used. After oral administration of the active diastereoisomer, a mean excretion of 43.25% was observed, whereas the inactive diastereoisomer gave a mean excretion of 22.5%. There was no significant difference in the celiac patients. The absorption of the active diastereoisomer was significantly higher in the control groups than in the celiac patients. After i.v. administration of the active diastereoisomer, 50% was collected in the first 24 hr urine collection. However, the entire administered dose (104%) of the inactive diastereoisomer was collected over the same period. These results show that in man the reduced biologically active folate is preferentially reabsorbed by the kidneys and/or taken up by the body tissue stores. Since the 2 diastereoisomers are chemically inseparable, the preferential treatment of the active form appears to involve a carrier-mediated process.

0056 FOOD IRON ABSORPTION IN MAN. II. ISOTOPIC EXCHANGE OF IRON BETWEEN LABELED FOODS AND BETWEEN A FOOD AND AN IRON SALT. *(E.)* Bjorn-Rasmussen, E.; Hallberg, L.; Walker, R. B. (Dept. Med., Goteborg, Sweden). *Am. J. Clin. Nutr.* 26(12): 1311-1319, 1973.

MOTILITY

0070 THE ACTION OF CAERULEIN ON GASTROINTESTINAL PROPULSION IN MICE. *(E.)* Piccinelli, D.; Ricciotti, F.; Catalani, A.; Sale, P. (Inst. Pharmacol., Univ. Rome, Italy). *Naunyn Schmiederbergs Arch. Pharmacol.* 279(1):75-82, 1973.

The effects of caerulein, a decapeptide amide present in the skin of *Hyla Caerulea* as well as other Australian Hylae, on the intestinal motility of Swiss mice were studied. A technique was adopted utilizing a photoluminescent pigment as a detector of the intestinal propulsion. Caerulein at doses of 1-5 µg/kg enhanced intestinal motility. Caerulein at doses of 20-40 µg/kg inhibited intestinal motility. A separation of the 2 effects was successful and it was determined that the enhancing effect was localized in the intestine, while the inhibitory effect was displayed at the gastric level.

0071 THE CONTINUOUS WITHDRAWAL METHOD FOR THE QUANTITATIVE ANALYSIS OF THE LOWER OESOPHAGEAL SPHINCTER (LES) IN HUMANS. *(E.)* Waldeck, F.; Jennewein, H. M.; Siewert, R. (C. H. Boehringer Sohn, Ingelheim, Germany). *Eur. J. Clin. Invest.* 3(4):331-337, 1973.

The continuous withdrawal method, successfully used in animal experiments for recording pressure profiles in the lower esophageal sphincter, was applied for the first time in human studies. A catheter with 4 side holes, serving as a pressure transmitter, was continuously withdrawn from the stomach at a constant speed (6 mm/sec) while constantly perfused (5 ml/min.). This procedure has numerous advantages, particularly for quantitative analysis, when compared to both the stepwise pull-through method and an open-side catheter lying stationary in the sphincter. The profiles obtained using the continuous withdrawal method are remarkable for their definition. Displacements are eliminated, and the pressure maximum can be definitely determined even if there is a shift in the area of maximum pressure. Pressure profiles of the lower esophageal sphincter taken with the withdrawal method in 20 conscious subjects usually showed a gradual, and then a more rapid increase from aboral to oral. After reaching a maximum value the profiles decreased steeply and changed into subzero pressures. The maximum pressure taken from the pressure profiles of 20 subjects, the mean value of all experiments, was 19 ± 7.3 mm Hg with a mean sphincter length of 3.4 ± 0.6 cm. The pressure profiles could be recorded at intervals as short as 0.5-2 min without appreciable irritation of the sphincter. The continuous withdrawal method was especially efficient, even after an increase of the sphincter tone induced by pentagastrin (0.6 µg/kg, i.v.). The mean results of the experiments in 6 test subjects showed the maximum pressure in the lower esophageal sphincter increased from 13 ± 6.3 mm Hg to 44.2 ± 11 mm Hg 1 min. after the injection and the mean sphincter length increased from 3.9 ± 1.2 cm to 5.3 ± 1.4 cm. These effects subsided after 7-10 min. Pressure profiles thus obtained, combined with supplementary measurements, indicated that pentagastrin shifts the maximum pressure area in the oral direction.

0072 ENHANCEMENT OF Ca-CONTRACTIONS BY CATECHOLAMINES AND TEMPERATURE DEPENDENCY IN THE DEPOLARIZED TEANIA COLI OF THE GUINEA PIG. *(E.)*

Ohashi, H.; Ohga, A.; Saito, K. (Fac. Vet. Med., Hokkaido Univ., Sapporo, Japan). *Jap. J. Pharmacol.* 23(4):467-477, 1973.

Guinea-pig taeniae coli suspended in a depolarizing solution without calcium responded to calcium by a contraction. The effects of adrenaline, noradrenaline, and isoprenaline on the contactile response were investigated at 20 C and at 37 C. Contractile response to calcium was not affected significantly by adrenaline and noradrenaline, but was reduced by isoprenaline at 37 C. At 20 C, all 3 catecholamines inhibited calcium-contraction. The sequence of potency in producing the inhibition was isoprenaline, adrenaline, noradrenaline, the same sequence as related to beta-receptor mediated responses. A beta-receptor blocking agent markedly reduced or abolished the inhibitory effects, and consequently the calcium-contraction was enhanced by adrenaline and noradrenaline at 37 C. An alpha-receptor blocking agent increased the inhibitory effects so that adrenaline and noradrenaline reduced the calcium-contraction at 37 C. The order of potency in producing the inhibition after alpha-receptor blockade was unchanged. It was concluded that the stimulatory effect is mediated by alpha-receptor activation and the inhibitory effect by beta-receptor activation. After beta-receptor blockade and at 37 C, adrenaline and noradrenaline applied after calcium caused further tension. The contractile response to adrenaline resembles the slow component of the actylcholine-induced contraction, regarding time course and susceptibility to removal of calcium from the extracellular medium. Adrenaline enhanced the calcium-contraction to the same extent before and after frequent exposures to acetylcholine to deplete cell-bound calcium. The enhancement of the calcium-contraction by adrenaline and noradrenaline may be dependent on increased permeation of calcium ions across the cell membrane.

0073 COLONIC MOTILITY IN THE CAT III. INFLUENCE OF HYPOTHALAMIC AND MESENCEPHALIC STIMULATION.

(E.) Rostad, H. (Inst. Neurophysiol., Univ. Oslo, Norway). *Acta Physiol. Scand.* 89(1):104-115, 1973.

Colonic motility was studied using sensitive extraluminal strain-gauge transducers in lightly anesthetized cats following electrical stimulation of hypothalamic and mesencephalic structures. Stimulation of various structures of the hypothalamus gave the following results. The sympatho-inhibitory area in the anterior hypothalamus increased colonic activity concomitantly with a fall in blood pressure. The ventral anterior and lateral hypothalamus produced excitatory colonic effects, usually associated with a rise in blood pressure. Similar effects were obtained from the dorsal part of the ventromedial hypothalamic nucleus. Stimulation of the ventral part of the hypothalamus, generally coinciding with the course of the medial forebrain bundle, and the ventral part of the ventromedial nucleus, resulted in inhibitory colonic effects. Stimulation of various structures of the mesencephelon gave the following results. The central gray substance, red nucleus, and reticular substance elicited increased colonic effects, most conspicuous in the proximal part of the colon, usually associated with a rise in blood pressure. Points within the central tegmental tract and the medial lemniscus resulted in inhibition of colonic motility.

0074 MODE OF ACTION OF CHOLECYSTOKININ AND RELATED PEPTIDES ON GALLBLADDER MUSCLE.

(E.) Yau, W. M.; Makhlouf, G. M.; Edwards, L. E.; Farrar, J. T. (Med. Coll. Virginia, Richmond). *Gastroenterology* 65(3):451-456, 1973.

The effect of cholecystokinin, octapeptide-cholecystokinin, caerulein, and pentagastrin on guinea pig gallbladder muscle contraction was investigated *in vitro*. Concentration-response curves were constructed for each peptide and shown to obey Michaelis-Menten type kinetics. Maximal responses were similar, indicating that the efficacies of all 4 peptides were equal. In this instance, therefore, the concentrations required to elicit a given (half-maximal) response could be held to represent molar potency. Accordingly, it was calculated that the octapeptide fragment of cholecystokinin and caerulein were, resp., 10 and 2 times more potent than cholecystokinin while pentagastrin was 1800 times less potent. Response could not be altered by anticholinergic, anti-adrenergic, and depolarizing agents, or tetrodotoxin, from which it was concluded that cholecystokinin and related peptides exerted their action directly on gallbladder muscle.

0075 CHARACTERIZATION OF ANGIOTENSIN RECEPTORS IN VASCULAR AND INTESTINAL SMOOTH MUSCLES.

(E.) Park, W. K.; Regoli, D.; Rioux, F. (Central Hosp., Univ. Sherbrooke, Canada). *Br. J. Pharmacol.* 48(2):288-301, 1973.

Analogues of angiotensin II (AT_{II}) were used to characterize receptors for AT_{II} in intestinal (rat stomach strip, rat colon) and vascular (rabbit aorta) smooth muscles. Two types of compounds were chosen: (a) agonists with reduced potency, in which 4-Tyr, 6-His, or 7-Pro had been substituted with L-Ala or with Gly and 1-aminocyclopentane carboxylic acid and (b) competitive antagonists (8-Gly-AT_{II}, 8-Leu-AT_{II}). Replacement of 4-Tyr, 6-His, and 7-Pro with L-Ala decreases the potency, but does not influence the maximum effect of the analogue, while substitution of the same residue with Gly and 1-aminocyclopentane carboxylic acid reduces both potency and maximum effect. Compounds showing full size maximum responses were chosen to establish the following order of potency on the three preparations: $AT_{II} > 4\text{-Phe-}AT_{II} > 7\text{-Ala-}AT_{II} > 6\text{-Ala-}AT_{II} > 4\text{-Ala-}AT_{II}$. The 4 derivatives of angiotensin II were inactive on tissues desensitized with AT_{II}. The responses to 5-hydroxytryptamine, acetylcholine, and noradrenaline were not significantly modified, except for the rat colon. pA_2 values for the 2 competitive antagonists against AT_{II} and 4-Phe-AT_{II} were estimated in the 3 preparations by the cascade superfusion technique. For comparison, pA_2 values were also estimated in rat stomach strips and rabbit aortas suspended in a normal organ bath. The similarities of the pA_2 values obtained in 2 series of experiments indicate that the cascade superfusion technique is suitable for this type of study and the receptor for AT_{II} in the 3 tissues may be the same. It is suggested that receptors for AT_{II} in intestinal and vascular smooth muscles may be identical, because the order of potency of various agonists follows the same pattern, the agonists are inactive on tissues desensitized with AT_{II}, and pA_2 values for competitive antagonists are similar in the 3 preparations.

0076 MOTOR RESPONSES OF THE SIGMOID COLON AND RECTUM TO EXOGENOUS CHOLECYSTOKININ AND SECRETIN. *(E.)* Dinoso, Jr., V. P.; Meshkinpour, H.; Lorber, S. H.; Gutierrez, J. G.; Chey, W. Y. (Temple Univ. Health Sci. Ctr., Philadelphia, Pa.). *Gastroenterology* 65(3):438-444, 1973.

The effects of exogenous cholecystokinin and secretin on motor activity of the sigmoid colon and rectum were studied in 10 subjects (5 males and 5 females aged 22-68 yr). Cholecystokinin (0.5-2.0 U/kg/hr, i.v.) stimulated and secretin (0.5-2.0 U/kg/hr, i. v.) inhibited basal motor activity of the sigmoid, as measured by intraluminal pressure changes. In addition, cholecystokinin-induced motor activity of the sigmoid colon was inhibited by secretin. Neither cholecystokinin nor secretin influenced motor activity of the rectum.

0077 THE ELECTRICAL AND MOTOR ACTIONS OF GASTROINTESTINAL HORMONES ON THE DUODENUM IN MAN. *(E.)* Waterfall, W. E.; Duthie, H. L.; Brown, B. H. (Dept. Surg., Univ. Sheffield, England). *Gut* 14(9):689-696, 1973.

Electrical and motor activity was recorded from the duodenum in 16 conscious human subjects in resting conditions to study the actions of gastrointestinal hormones. A negative pressure of 20 cm Hg was applied to the proximal end of the probe to attach the electrode to the bowel wall. An open tip catheter system was used to detect changes in intraluminal pressure, the opening of the fine polythene tube being brought out opposite the electrode. Pentagastrin in doses of 1.0 and 6 μg/kg/hr was given by continuous i.v. infusion 8 patients. Secretin was given by continuous i.v. infusion in separate tests in 0.25 and 1 U/kg/hr doses to 6 patients. In the fasting state during saline infusion in 16 patients, the frequency of the pacesetter potential varied between 11.2 and 12.6 cycles/min. Motor waves were recorded in all subjects. The percentage activity in the fasted state ranged from 1-45%. Secretin in a dose of 1 U/kg/hr and pentagstrin in a dose of 6 μg/kg/hr produced a significant effect on the frequency of action potential bursts. Secretin reduced, and pentagastrin increased, the bursts of action potentials. These changes in action potential frequency were in direct proportion to changes in motility during infusion with each hormone. The frequency of the pacesetter potential did not change significantly during infusion with either hormone.

0078 ACTION OF XYLAMIDE ON GASTROINTESTINAL MOTOR ACTIVITY IN ANIMALS AND ANIMAL ORGANS. *(E.)* Benzi, G. M.; Arrigoni, E.; Panceri, P.; Panzarasa, R.; Berte, F. (Dept. Pharmacol., Univ. Pavia, Italy). *Digestion* 9(2):149-165, 1973.

The action of xylamide on the gastrointestinal tract, activated by electrical or chemical stimulation, was studied *in vitro* in the guinea pig, cat, and mongrel dog; and *in situ* in mongrel and beagle dogs. In the guinea pig isolated stomach, transmural electrical stimulation produced a rapid contraction followed by an after-relaxation when stimulation ceased; the magnitude of the after-relaxation depended on the number of shocks delivered and on the frequency of stimulation, the higher the rate, the greater the magnitude. Xylamide (1.25-40 x 10^{-5}g/ml) into the organ bath reduced the contractor response to transmural and vagal stimulation. In the guinea pig isolated ileum, the transmural stimulation induced a rapid contraction followed by a rapid relaxation when stimulation was stopped. Xylamide (5-80 x 10^{-5}g/ml) induced a relaxation of the contraction. Xylamide inhibited the effects of acetylcholine, histamine, nicotine, and 5-hydroxytryptamine on the longitudinal muscle. In the guinea pig isolated terminal colon, stimulation of pelvic nerves induced a rapid contraction followed by a rapid relaxation. Transmural stimulation induced a triphasic response: contraction, relaxation, and inhibition. Xylamide (2-16 x 10^{-4}g/ml) reduced the contractions. Xylamide did not affect the action of adrenergic blocking agents. Transmural electrical stimula- of the isolated guinea pig and cat gall bladder produced a rapid contraction sometimes followed by an after relaxation. Xylamide (0.5-16 x 10^{-4} g/ml) induced either a progressive or a rapid inhibition of the contractions. Transmural electrical stimulation of the dog isolated bile duct produced a rapid contraction of the longitudinal smooth muscles and a decrease of the intracholedochal flow, followed by a rapid return to control conditions. Xylamide (1-8 x 10^{-4}g/ml) decreased the magnitude of the response after 30-60 min of contact. Xylamide flowing through the terminal bile duct (5-40 x 10^{-5}g/ml) induced an increase of the biliary flow, accompanied by a slight decrease of the duodenal motility, without change of the duodenal tone in *in situ* experiments in dogs.

0079 THE INTERACTION OF GLUCAGON AND PENTAGASTRIN ON THE LOWER OESOPHAGEAL SPHINCTER IN MAN AND DOG. *(E.)* Jennewein, H. M.; Waldeck, F.; Siewert, R.; Weiser, F.; Thimm, R. (Dept. Pharmacol., C. H. Boehringer Sohn, Ingelheim, Germany). *Gut* 14(11):861-864, 1973.

The effect of glucagon on the pressure inside the lower esophageal sphincter was studied in 24 conscious human volunteers (20-25 yr old), 10 patients suffering from achalasia (40-65 yr), and 12 anesthetized dogs. Single i.v. injections of glucagon cause a decrease in sphincteric pressure in both man and dog. Doses of 60 μg/kg in man and 100 μg/kg in dogs yield a maximum decrease in sphincteric tone. A continuous i.v. infusion of glucagon also causes a reduction in sphincteric tone. A glucagon infusion of 0.5 mg/kg hr reduces sphincteric pressure in dogs almost completely. Glucagon flattens the dose response curve of pentagastrin, the degree of flattening depends on the dose of glucagon administered. In humans, a glucagon infusion (750 μg/kg hr) resulted in a 40% decrease in sphincteric pressure. In 12 experiments on isolated muscle strips from the lower esophageal sphincter of dogs, the tension of the strips was regularly reduced by applying 10^{-8} and 10^{-5} g/ml glucagon. I.v. injection of 60 μg/kg glucagon in the 10 patients decreased the elevated resting pressure 3 min after administration. It is concluded that glucagon decreases the maximum pressure inside the lower esophageal sphincter in man and dog, when given as single injections or as continuous infusions.

0080 POSTOPERATIVE ILEUS IN THE RAT: PHYSIOPATHOLOGY, ETIOLOGY AND TREATMENT. *(E.)* Dubois, A.; Weise, V. K.; Kopin, I. J. (Natl. Inst. Mental Health, Bethesda, Md.). *Ann. Surg.* 178(6):781-786, 1973.

Ileus was induced in male Sprague-Dawley rats by laparotomy followed by intestinal exteriorization for 30 min. Sympathetic neuronal function and motor activity of the gastrointestinal tract during the postoperative phase were assessed directly by measurement of norepinephrine-^{14}C synthesis from Tyrosine-^{14}C and propulsion of a ^{51}Cr test meal. Both gastric emptying and small intestinal propulsive activity were impaired during the postoperative phase. Increased norepinephrine synthesis was observed in the digestive tracts of operated animals but not in their hearts. Chemical sympathectomy with 6-hydroxydopamine (150 mg/kg i.v.) prevented the appearance of postoperative ileus. The findings are consistent with the hypothesis that postoperative ileus is related to intestinal sympathetic hyperactivity occurring during the postoperative period.

0081 MECHANICS OF SPHINCTER ACTION: STUDIES ON THE LOWER ESOPHAGEAL SPHINCTER. *(E.)* Biancani, P.; Goyal, R. K.; Phillips, A.; Spiro, H. (Dept. Int. Med., Yale Univ., New Haven, Conn.). *J. Clin. Invest.* 52(12):2973-2978, 1973.

The mechanical factors involved in the genesis of lower esophageal sphincter pressure were studied in 99 Sprague-Dawley rats. Various degrees of circumferential stretch were applied by introducing probes of different diameters in the rat lower esophageal sphincter *in vivo*. The intraluminal pressure produced by the lower esophageal sphincter around each probe was measured and pressure-diameter curves were constructed during resting state, contraction produced by electrical stimulation, and relaxation produced by esophageal distension. The intraluminal pressure at an inside diameter of 0.5 mm was similar to that at inside diameter of 3.2 mm. This was true for the sphincter at rest as well as upon electrical stimulation. The pressure diameter curve, however, was sigmoid in shape with a decline and then an increase followed by decline in pressure again with increasing diameters. The ratio of wall thickness to inside radius or the magnification factor varied with inside diameters and this ratio increased steeply at small inside diameters. The tension diameter curves of the sphincter muscle showed that optimal tension development occurred not near sphincter closure but at a much wider diameter of 3.2 mm and that this muscle developed tension even at small luminal diameters. This behavior of the sphincter muscle ensures effective intraluminal pressure over a wide range of luminal diameters.

SECRETION AND METABOLISM

0099 SALIVARY AND PANCREATIC AMYLASE: ELECTROPHORETIC CHARACTERIZATIONS AND GENETIC STUDIES. *(E.)* Merritt, A. D.; Rivas, M. L.; Bixler, D.; Newell, R. (Indiana Univ. Med. Ctr., Indianapolis). *Am. J. Hum. Genet.* 25(5):510-522, 1973.

Discontinuous sheet polyacrylamide gel and agar gel electrophoresis were utilized to demonstrate the origin of amylase phenotypes and to identify 7 salivary (Amy$_1$) and 3 pancreatic (Amy$_2$) amylase phenotypes that are expressions of 2 closely linked loci on chromosome 1. The combined frequencies of the Amy$_1$ variants in Caucasian Americans and Afro-Americans is .0073 and .0769, resp. The frequency of Amy$_2$ B in Caucasian Americans and Afro-Americans is .105 and .029, resp. The Amy$_2$ C phenotype is present only in Americans of African descent at a frequency of .047 and is found also in black Africans. Of 4 new variants, Amy$_1$ F was found exclusively in 1 Chinese. The other 3 new variants determined in this study, Amy$_1$ E, Amy$_1$ G, and Amy$_2$ C were present only in these of black African descent. Family data demonstrate an autosomal dominant mode of inheritance for each of the variants. The use of agar gel electrophoresis as a single system to type Amy$_1$ and Amy$_2$ phenotypes is to be avoided.

0100 DETERMINATION OF IMMUNOGLOBULINS IN HUMAN GASTROINTESTINAL SECRETIONS AND A STUDY OF SOME FUNCTIONS OF ANTIBODIES. *(Fr.)* de Kalbermatten, A.; Girard, J. P. (Cantonal Hosp., Geneva, Switzerland). *Arch. Fr. Mal. App. Dig.* 62(1):33-52, 1973.

Quantitative determinations of IgA, IgG, and IgM were made on duodenal juice after stimulation with secretin (1 U/kg i.v.) or olive oil (40 ml) on 69 normal subjects and patients with a variety of gastrointestinal diseases. The results varied widely, particularly for IgG and, to a lesser extent, for IgM. The IgG/IgA ratio was about 1 comapred to 1/6 in the serum, while the IgG/IgM ratio was 0.75 in contrast to 15/1 in the serum. Concentrations of IgA were significantly increased in cholecystitis as were IgM concentrations in hepatitis, and might be related to the pathogenesis of these diseases. In normal subjects the β_1-C component of complement was detected in 39 of 45 specimens tested (5-104 mg/100 ml; mean of 30 mg/100 ml), and lysozyme was present in 36 of 64 specimens (mean of 2.8 μg/liter). The secretory piece was detected in almost all specimens from normal subjects, suggesting that IgA is exocrine in nature. Opsonin activities, determined morphologically and by the nitroblue tetrazolium method with *Escherichia coli*, *Salmonella typhi*, and *Staphylococcus aureus*, were significantly increased in the presence of complement. Anti-*E. coli* antibodies were detected in only 2 of 40 normal specimens by double diffusion in agar, while titers of 1:2 to 1:2048 were obtained on 52 of 72 specimens by passive hemagglutination. The hypothesis that this phenomenon is due to acquired immunity was tested by immunizing 12 infants p.o. with a polyvalent vaccine of pathogenic *E. coli* strains. Significant increases occurred in the titers of anti-*E. coli* antibodies in the stools and duodenal juice, and these increases were accompanied by an increase in IgA in duodenal juice which was significantly greater than increases in IgG and IgM. These studies strongly suggest that immunoglobulins in gastrointestinal secretions play an important role in protecting against pathogenic bacteria present on the mucosal surface.

0101 INFLUENCE OF SECRETIN ON SALIVARY MUCOUS SECRETION IN MAN. *(E.)* Descos, F.; Andre, F.; Lambert, R.; Andre, C. (Hosp. E. Herriot, Lyon, France). *Digestion* 9(3):199-204, 1973.

The influence of secretin on salivary mucous secretion was studied in 18 male subjects without any rhinopharyngeal or gastrointestinal disease. Saliva was collected for 2 hours in eight 15-min samples following overnight fasting. In one group of patients, saliva was collected in basal conditions; in the second group, saliva was collected as patients were steadily chewing parafilm. No significant variation in volume or outputs of fucose, hexosamine, or bicarbonate was observed in either the resting (saline, 100 ml/hr, was infused i.v. throughout the experiment) or stimulated (1250 CU/kg hr of secretin was added to saline) condition.

SECRETION AND METABOLISM

Stomach

0107 IMMUNOCHEMICAL STUDY OF FETAL PEPSINOGEN. *(Fr.)* Hirsch-Marie, H.; Touboul, J. P. (St. Antoine Hosp., Paris, France). *Biol. Gastroenterol. (Paris)* 6(1):55-62, 1973.

Pepsinogen was analyzed in ether-acetone extracts prepared from the stomachs of 34 embryos and fetuses obtained between the 2nd and 9th months of pregnancy. The results were compared with those obtained on extracts prepared from the gastric mucosa and gastric juice from adults and newborns. Only 1 zone of proteolytic activity with an optimum pH of 2.0 was present on agar gel electrophoresis of fetal extracts obtained during the first 8 months of pregnancy. During the 9th month, 2 additional bands appeared closer to the anode. By means of immunoelectrophoresis the protease found in fetuses during the first 8 months was identified as the enzyme obtained by activation of pepsinogen P IV, already described as a constituent of normal adult gastric mucosa. This pepsinogen was present in far larger amounts in the fetal than in the adult stomach. Although the amount of this pepsinogen was lower in newborns than in fetuses, it did not completely disappear, suggesting that repression of the genes responsible for its synthesis is incomplete.

0108 DESULFATION OF SULFATED POLYANIONS BY RAT GASTRIC MUCOSA. *(E.)* Liau, Y. H.; Horowitz, M. I. (New York Med. Coll., Valhalla). *Proc. Soc. Exp. Biol. Med.* 144(1):13-16, 1973.

The desulfation of sulfate polyanions by rat gastric mucosa was studied in 5 adult male Sprague-Dawley rats injected i.p. with 150 μC $Na_2{}^{35}SO_4$.

Fractions soluble in 0.125 M, 0.7 M, and 1.4 M aqueous $MgCl_2$ were obtained from the cetylpyridinium chloride (CPC) precipitation-fractional salt extraction procedure applied to the papain digest of stomach and duodenum scrapings. The following partition of radioactivity was found for these fractions: 130,000, 1,000,000, and 105,000 cpm, resp. The preparation of rib chondroitin sulfate was obtained in a yield of 8 mg/g cartilage and exhibited a specific activity of 9.1×10^5 cpm/mg of preparation. The preparation contained 84% chondroitin 4-sulfate, 8% chondroitin 6-sulfate, and 8% other polyanion sulfates. Fractionation with $(NH_4)_2SO_4$ afforded enrichment of the sulfatase and depolymerase enzymes in the precipitate obtained at 60-72% saturation. Enzyme activities were stable for at least 2 months when stored in pH 4.0 acetate buffer under toluene at 5 degrees.

0109 INHIBITION OF HUMAN GASTRIC SECRETION BY PROSTAGLANDIN. *(E.)* Carter, D. C.; Karim, S. M. M.; Bhana, D.; Ganesan, P. A. (Univ. Edinburgh, Scotland). *Br. J. Surg.* 60(10):828-831, 1973.

The inhibition of human gastric secretion by synthetic prostaglandin was studied in healthy male volunteers without previous dyspeptic history. In 11 tests 200 μg of the synthetic analogue prostaglandin 15(R)15 methyl-E_2 methyl ester were given p.o. to assess its effect on basal acid secretion; in 9 tests the same dose was administered by bolus i.v. injection. In 12 subjects, 200 μg of the analogue were given p.o. to challenge the acid secretion induced by pentagastrin (6 μg/kg i.m.). A marked and sustained reduction in acid secretion was noted in all the cases after the oral administration of 200 μg of the analogue. In 8 cases the aspirate became alkaline after instillation of the dose. The mean 3-hr acid output in control studies was reduced by 76% by prostaglandin administration. In only one subject was a marked and sustained rise in the pH of the aspirate observed following i.v. prostaglandin injection. The mean 3-hr output in control studies was reduced only by 24.5% following i.v. prostaglandin injection. In 11 of the 12 subjects, the maximal acid output was lowered by prior instillation of the prostaglandin analogue. It is concluded that prostaglandin is a potent inhibitor of basal and pentagastrin-induced acid secretion when given p.o. If the absence of side effects is confirmed, prostaglandin 15(R)15 methyl-E_2 methyl ester may be a valuable aid in management of peptic ulcer diathesis.

0110 METABOLIC CLEARANCE AND DISAPPEARANCE RATES OF SYNTHETIC HUMAN GASTRIN IN MAN. *(E.)* Schrumpf, E.; Semb, L. S.; Vold, H. (Ulleval Univ. Hosp. Oslo, Norway). *Scand. J. Gastroenterol.* 8(8):731-734, 1973.

Synthetic human gastrin (SHG) was infused i.v. at a constant rate for 2 hours in 5 volunteers. Gastrin concentration was determined by radioimmunoassay in plasma samples before, during, and at frequent intervals after the infusion. Gastric acid output was also measured. During the infusion the gastrin concentration and the gastric acid output reached a plateau level after approximately 30 min. After stopping the infusion there was a rapid decline in the plasma concentration of gastrin. Regression analysis indicated that the disappearance curve was at least bi-exponential, which means that the removal of gastrin is not proportional to the concentration. The mean metabolis clearance rate/kg was 9.1 ml/min. The metabolic clearance rate of SHG in this study is considerably smaller than previously found in the dog (70 ml/min/kg), suggesting that heterologous gastrin is broken down more rapidly than homologous gastrin.

0111 INHIBITION OF MEAL-INDUCED GASTRIC ACID SECRETION BY GLUCAGON. *(E.)* Lin, T. M. (Lilly Res. Labs., Indianapolis, Ind.). *Arch. Int. Pharmacodyn. Ther.* 204(2):361-367, 1973.

The secretion of hydrochloric acid from vagally innervated and denervated gastric pouches in dogs in response to a 200 g test meal was inhibited by a single injection of glucagon (10 μg/kg for 60 to 90 min. The acid response to a 400 g test meal was inhibited for at least 4 1/2 hr during continuous i.v. infusion of glucagon (12.5 μg/kg/hr). The same response was either unaffected or very slightly inhibited by continuous infusion of a solution of hypertonic glucose. The inhibitory effect of glucagon was not related to its action on blood sugar or the tissue utilization of sugar. The results suggest a direct action of the hormone on the gastric mucosa. Previous results indicate that in addition to an action on gastric mucosal blood flow, glucagon has a direct metabolic action on the acid producing cells under the influence of pentagastrin.

0112 BICARBONATE SECRETION IN THE HUMAN STOMACH. *(E.)* Andre, C.; Bruhiere, J.; Vagne, M.; Lambert, R. (Hosp. Ed. Herriot, Lyon, France). *Acta Hepatogastroenterol.* 20(1):62-69, 1973.

Electrolyte output of bicarbonate, sodium, chloride, and potassium was studied in 20 healthy subjects (17 males and 3 females) after a gastric load by a buffered glycine test meal. The outputs were compared in basal conditions and after injection of betazole (1.5 mg/kg, s.c.). Under the influence of betazole, bicarbonate and chloride output reached 235-266% and 373-580% of basal values, resp. Thus, bicarbonate secretion in the human stomach is not steady and increases when the fundic mucosa is stimulated. Sodium secretion was observed only after betazole administration. Calculation of concentrations demonstrated high values for chloride and bicarbonate explained by the trapping effect of glycine buffer on hydrogen ions.

0113 A PHYSIOLOGICAL INHIBITOR OF GASTRIC SECRETION, THE ACTIVATION PEPTIDE OF TRYPSINOGEN. *(E.)* Abita, J. P.; Moulin, A.; Lazdunski, M.; Hage, G.; Palasciano, G.; Brasca, A.; Tiscornia, O. (Dept. Biochem., Univ. Nice, France). *FEBS Lett.* 34(2):251-255, 1973.

Bovine trypsinogen was converted to trypsin. Isolation of the activation peptide of trypsinogen (peptide I) was carried out by filtration through Sephadex G-25 and ion-exchange chromatography. Surgical preparation, chronic gastric and pancreatic Thomas cannulae, was completed on 7 dogs. A constant rate infusion (100 ml/hr, i.v.) of pentagastrin (2 μg/kg/hr), human gastrin I (2 μg/kg/hr), or hog gastrin (2 μg/kg/hr) was used to stimulate gastric secretion. Once a plateau acid response was achieved, peptide I or control peptides were given i.v. or intraduodenally in doses from 300-2500 μg. Peptide I (700 μg, intraduodenally) rapidly inhibited the acid response to pentagastrin (2 μg/kg/hr). This inhibition remained significant for 1 hr. A second infusion produced a further inhibition of gastric secretion. A temporary inhibition of the acid response to 2 μg/kg/hr of hog or human gastrin I was also observed with 500 μg peptide I infused intraduodenally. Introduction of peptide I i.v. also produced inhibition. The inhibition of gastric juice secretion by the activation peptide of trypsinogen emphasizes that both components of the pancreatic secretion, the alkaline and the proteic, are important in the regulation of pH at the duodenal level. The former neutralizes the hydrochloric acid entering the duodenum. The latter, via the activation peptide of trypsinogen, counteracts the gastrin stimulation of the stomach. It is suggested that this activation peptide is one of the links connecting duodenal activation of the zymogens and their secretion by the pancreas.

0114 THE EFFECT OF A NEW DEPOT SECRETIN ON THE GASTRIC AND PANCREATIC SECRETIONS IN HUMANS. *(E.)* Demling, L.; Classen, M.; Koch, H.; Domschke, W. (Dept. Med., Univ. Erlangen Nuremberg, Germany). *Acta Hepatogastroenterol.* 20(4):324-330, 1973.

Secretin stimulates the pancreas to secrete water and bicarbonate. At the same time it inhibits the secretion of acid but promotes the production of pepsin in the stomach. Secretin (10 u/kg, s.c.), coupled to polyphloretin phosphate and a peptide mixture, was administered to 3 male volunteers, aged 22-61 yr, and led to production of 1.5-2.5 liters of pancreatic secretion within 10 hr containing 187-190 mEq of bicarbonate. The duration of the effect was 9-10 hr. The content of acid and pepsin in the stomach dropped considerably over the same period. The gastric production of acid and pepsin could not be determined accurately because of a duodenogastric reflux after the administration of secretin. These investigations form part of a clinical study of the use of secretin in the treatment of duodenal ulcer.

0115 INCREASED PRODUCTION OF CYCLIC AMP IN GASTRIC TISSUE BY STIMULATION OF HISTAMINE$_2$ (H_2)-RECEPTORS. *(E.)* Karppanen, H. O.; Westermann, E. (Med. Clin. Hannover, Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 279(1):83-87, 1973.

Histamine stimulated the production of cAMP by minced gastric tissue of guinea pigs in a dose-dependent manner in the presence of theophylline (10^{-3} M). This stimulation was competitively inhibited by the histamine$_2$-receptor blocking agent burimamide (3.3 X 10^{-4}M) but the histamine$_1$-receptor blocking agent diphenphydramine (3.3 X 10^{-4}M) only shifted the dose-response curve slightly to the right. Since the histamine-stimulated secretion of acid by the stomach is also inhibited by blockade of H_2-receptors but not by blockade of H_1-receptors, these findings support the role of cAMP as the mediator in the action of histamine on the secretion of gastric acid. The antihypertensive drug clonidine (2X10^{-6}moles/kg) increased the secretion of gastric acid in the stomachs of male Wistar rats in apparently the same way as histamine did, i.e. stimulation of H_2-receptors and subsequent increase in the formation of cAMP. During an *in vitro* study on cAMP production by gastric tissue of guinea pigs, clonidine (10^{-3}M) did not significantly increase production. When theophylline (10^{-3}M) was present, the stimulatory action of clonidine was greatly enhanced.

0116 CORRELATION BETWEEN THE OUTPUTS OF PEPSIN AND HCl BY ISOLATED, EX VIVO PERFUSED, CANINE STOMACH STIMULATED WITH HUMORAL AND CHOLINERGIC DRUGS. *(E.)* Kowalewski, K.; Kolodej, A. (Surg. Med. Res. Inst., Univ. Alberta, Edmonton, Canada). *Pharmacology* 9(6):325-335, 1973.

Gastric pepsin and hydrochloric acid were studied in the totally isolated canine stomach, perfused with homologous blood. Secretion was stimulated for several hours by intra-arterial infusion of histamine, pentagastrin, and bethanechol chloride, separately or combined. The ratio of outputs of pepsin and hydrochloric acid (P-O/HCl-O) were calculated. The relation between paired values of pepsin (mg/30 min) and H^+ (mEq/30 min) was analyzed by computer and the linear correlation was calculated. Bethanechol chloride emerged a very strong stimulant of pepsin and high (P-O/HCl-O) ratios were found in the presence of cholinergic stimulation applied separately or combined with the humoral secretagogues used. Bethanechol chloride potentiated the effect of histamine and pentagastrin on pepsin secretion. No potentiation was observed when histamine was combined with pentagastrin. The relation between pepsin and acid expressed by (P-O/HCl-O) ratio depended on the secretagogue used. Linear regression lines satisfactorily characterized the relation between pepsin and H^+ outputs under all conditions of stimulation applied.

0117 EFFECTS OF SALICYLATE AND RELATED COMPOUNDS ON GASTRIC HCl SECRETION. *(E.)*

Kasbekar, D. K. (Georgetown Univ. Sch. Med., Washington, D.C.). *Am. J. Physiol.* 225(3):521-527, 1973.

Isolated bullfrog gastric mucosas were examined under a variety of conditions to study the effects of submucosal and mucosal instillation of salicylate and related compounds on H^+ secretory and electrical properties. Submucosal addition of salicylate caused a concentration-dependent decline of H^+ secretion and potential difference with a concomitant rise in mucosal resistance. These effects were almost completely reversible following drug washout, except at very low mucosal pH values. The inhibition of H^+ secretion and loss of potential difference following mucosal instillation of salicylate was accompanied by a fall in transmucosal resistance. Reversibility of these parameters following washout is a function of the pH of luminal bathing medium, concentration of the drug, and time of exposure. Mucosal ATP levels were reversibly reduced by submucosal salicylate and irreversibly by mucosal instillation of salicylic acid at low pH. Preliminary studies with isolated mitochondrial preparations indicated that salicylate inhibits rather than uncouples oxidative phosphorylation.

0118 GASTRIC EFFECTS OF CYCLOHEXIMIDE. *(E.)*

Henman, F. D. (Dept. Pharmacol., Univ. Dundee, Scotland). *Digestion* 8(4):299-307, 1973.

Cycloheximide (50 mg/kg, i.p.) reduced the volume and acid concentration of gastric secretion elicited from gastric dual-ligated female Sprague-Dawley rats by administration of insulin (1 IU, s.c.) or histamine (5 mg, s.c.). Cycloheximide reduced the volume of gastric secretion of gastric dual-ligated rats stimulated by pentagastrin (200 µg) in a depot preparation. Pepsin concentration was unaltered. Cycloheximide did not increase the gastric back diffusion of acid from the stomach. The pentagastrin-stimulated increase in gastric specific histidine decarboxylase activity was prevented by cycloheximide. It is concluded that gastric secretion of acid involves the synthesis of a protein other than histidine decarboxylase.

0119 CHANGES IN GASTRIC SECRETION IN RATS DURING RESTRAINT AND THE EFFECT OF PREMEDICATION WITH ANTICHOLINERGIC AND HYPOTHALAMIC DEPRESSIVE AGENTS. *(E.)*

Birnbaum, D.; Karmeli, F.; Wauku, S. Y. (Hadassah Univ. Hosp., Jerusalem, Israel). *Rend. Gastroenterol.* 5(1):1-5, 1973.

The effect of anticholinergic and hypothalamic depressive drugs on gastric secretion was tested in restrained rats with chronic gastric fistula and was compared to control collections obtained from the same rats under identical experimental conditions. Premedication with paragon (0.2 mg/100 g, s.c.), mesoridazine (1.0 mg/100 g, s.c.), or diazepam (1.0 mg/100 g, s.c.) reduced gastric secretion from the control value of 2.49 ml/3 hr into 0.71, 0.96, and 1.21 ml/3 hr, resp. Total acid output was similarly diminished from a control value of 0.203 mEq/3hr to 0.059, 0.093, and 0.088 mEq/3 hr, resp. In pyloric-ligated rats comparison between restrained and unrestrained animals did not show a significant difference in volume, acid output, and incidence of erosions. Comparison between pyloric-ligated rats and those with gastric fistula, both under restraint stress, revealed the latter group secreted significantly lower amounts of gastric juice and acid.

0120 EFFECT OF L-THYROXINE ON SECRETORY RESPONSE TO HISTAMINE IN EX VIVO CANINE STOMACH PERFUSED WITH HOMOLOGOUS BLOOD OF THYROIDECTOMIZED DOG. *(E.)*

Kowalewski, K.; Kolodej, A. (Dept. Surg., Univ. Alberta, Edmonton, Canada). *Am. J. Dig. Dis.* 18(10):873-880, 1973.

Gastrectomized and gastrectomized plus thyroidectomized supporting dogs were used to study the effect of L-thyroxine on the secretory response to histamine in an *ex vivo* canine stomach. When *ex vivo* stomachs were perfused with the blood of thyroidectomized animals and stimulated with histamine, the output of gastric juice and of H^+, and the concentration of H^+, were significantly lower than in control stomachs perfused with the blood of normothyroid animals. When L-thyroxine was infused into the gastric artery of *ex vivo* stomachs, stimulated with histamine and perfused with the blood of thyroidectomized dogs, normal output and concentration of H^+ in these stomachs was observed. The exact mechanism of action of the thyroid hormone or its metabolites on gastric secretion is not known. The parietal cell may have been affected directly by a stimulant, which was the metabolic result of the injected thyroid hormone. It is also possible that the thyroid hormone modified the responsiveness of the parietal cell to histamine. A third possibility is that the thyroid hormone normalized gastric secretion by preventing gastric edema and reduction of motility.

0121 INFLUENCE OF VAGOTOMY ON TISSUE GASTRIN LEVELS IN STOMACH AND PANCREAS IN RATS. *(E.)*

Becker, H. D.; Reeder, D. D.; Thompson, J. C. (Univ. Texas Med. Branch, Galveston). *Surgery* 74(5):778-782, 1974.

The influence of vagotomy on tissue gastrin levels in stomach and pancreas was studied in 32 male Wistar rats. In a control group either a simple laparotomy (8 rats) or a Heinecke-Mikulica pyloroplasty (8 rats) was done. In the test group (16 rats) a truncal vagotomy with pyloroplasty was done. Gastrin concentrations and total gastrin contents in the two control groups did not differ. At 8 weeks after truncal vagotomy, the mean gastrin concentration in the antrum increased from 6410 to 13,930 ng/g tissue. The mean total gastrin in the antrum increased from 1772 to 4489 ng at 8 weeks. This increase in total gastrin was the result not only of an increase in gastrin concentration, but also of a 20% increase in the mean weight of the antrum. Truncal vagotomy increased mean fundic gastrin concentration from 31 to 367 ng/g at 8 weeks, and the total content from 19 to 263 ng. The mean weight of the fundus was 6.5% higher 8 weeks after vagotomy than in the control group. After truncal vagotomy, the mean gastrin concentration in the pancreas increased from 1.17 to 2.83 ng/g tissue and the total gastrin content from 0.26 to 0.72 ng. The mean weight of the pancreas was not changed by vagotomy. Loss of acid inhibition may be responsible for the increased gastrin concentrations, and the increase in stomach weight may be due to the trophic action of the larger amounts of gastrin.

0122 THE PEPSINOGENS OF HUMAN GASTRIC MUCOSA.

(E.) Whitecross, D. P.; Armstrong, C.; Clarke, A. D.; Piper, D. W. (Dept Med., Univ. Sydney, Australia). *Gut* 14(11):850-855, 1973.

Pepsinogens of human gastric mucosa were studied in samples of mucosa uninvolved in gastric lesion from 25 patients, taken from sites adjacent to areas of mucosa which were identified as fundic, antral, or duodenal mucosa using histological techniques. Gel electrophoretic patterns showed 6 major bands and 4 minor bands of protease activity. All were present in fundic mucosa, only the two slowly moving bands were prominent in antral mucosa and only one, the most slowly moving of the six present in fundic mucosa, was present in duodenal mucosa. The histological tissue type and the electrophoretic pattern agreed in 6 of 9 samples with a fundic electrophoretic pattern, 3 of 5 with an antral electrophoretic pattern, and in both samples with a duodenal electrophoretic pattern. The number of major bands observed did not vary with disease, age, sex, and smoking habits. On column chromatography of fundic mucosal homogenates, 6 well-defined peaks were obvious. Subsequent electrophoresis of the concentrated fractions from each peak showed that each was formed by an electrophoretically distinct pepsinogen with slight contamination by the adjacent pepsinogens due to overlapping of the peaks. Each of the pepsinogens 1 to 4 gave rise to a single pepsin band on electrophoresis; pepsinogen 5 gave rise to 2 pepsin bands of equal activity. Pepsinogen 6 was insufficiently concentrated for any activity to be detected. Both pepsins from pepsinogens 2 and 4 gave rise to activity curves of similar overall shape in the region pH 1.2-2.0. However, in the region pH 2.3-3.5 the activity curves showed different pH optima, and although both pepsins had similar activity in the pH 1.2-2.0 region, the pepsin from pepsinogen 2 was markedly more active in the pH 2.2-2.8 region.

0123 ASSESSMENT OF THE RELATIONSHIP BETWEEN GASTRIC SECRETORY CAPACITY AND JEJUNAL BACTERIOLOGY.

(E.) Frederiksen, W.; Bruusgaard, A.; Thaysen, E. H. (Aalborg Hosp. Nord, Denmark). *Scand. J. Gastroenterol.* 31(3):353-359, 1973.

The effect of gastric acid secretion on the bacterial population of the proximal small gut was studied in 282 patients without evidence of intestinal stasis. Significant bacterial counts ($>10^4$/ml) were obtained in fasting jejunal aspirates from 35 of 46 patients with gastric peak acid outputs between 0 and 5 mEq H^+/hr from 18 of 66 patients with peak acid outputs between 6 and 15 mEq H^+/hr: and from 16 of 170 patients with peak acid outputs equal to or greater than 16 mEq H^+/hr. Of 55 patients with intestinal stasis 48 had significant bacterial counts in their jejunal aspirates. In these patients the contamination of the proximal small gut was apparently independent of the gastric secretory capacity. The bacterial species recovered from jejunal aspirates in both groups were in part identical with those commonly isolated from saliva and also included a narrow selection of the bacterial population of the colon. Among the later *Escherichia coli* and other species of Enterobacteriacteae prevailed whereas the anaerobes were infrequent. The results of this study support the view that the gastric barrier to ingested bacteria is a pH-hydrochloric acid-dependent mechanism. It is suggested that there may be a relation between gastric anacidity or hyposecretion and the pathogenesis of enteric infections.

0124 EFFECT OF CALCIUM AND CALCITONIN ON GASTRIN AND GASTRIC SECRETION IN CATS. *(E.)*

Becker, H. D.; Konturek, S. J.; Reeder, D. D.; Thompson, J. C. (Univ. Texas Med. Br., Galveston). *Am. J. Physiol.* 225(2):277-280, 1973.

Intravenous infusion of calcium (10-40 mg/kg/hr) into cats with chronic gastric fistulas brought about dose-related increases in the levels of serum gastrin and gastric acid secretion. The maximal acid secretory response to hypercalcemia was about 25% of the maximal acid response to pentagastrin (16 µg/kg/hr). Calcitonin (20 U/kg/hr, i.v.) strongly inhibited histamine-, pentagastrin-, and calcium-induced gastric secretion and suppressed calcium-induced hypergastrinemia without changing serum calcium levels. Antrectomy prevented calcium-induced hypergastrinemia and stimulation of gastrin secretion. Atropine infusion (100 µg/kg/hr) significantly inhibited calcium-induced release of gastrin and stimulation of gastric secretion. In cats, as in man, calcium may be important in the regulation of gastric secretion. Calcitonin apparently suppresses calcium-induced gastric secretion both by suppression of gastrin release and by direct inhibition of the parietal cell.

0125 STUDIES OF GASTROINTESTINAL INTERACTIONS. V. GASTRIC SECRETION AND DUODENAL REFLUX IN MAN AFTER A COMPOSITE MEAL. THE INFLUENCE OF GLUCOSE ON GASTRIC SECRETION, EMPTYING AND GASTRIC VOLUME.

(E.) Lagerlof, H. O.; Johansson, C.; Ekelund, K. (Karolinska Inst., Stockholm, Sweden). *Scand. J. Gastroenterol.* 8(8):735-742, 1973.

The influence of glucose on gastric secretion, emptying, and gastric volume was studied in 7 healthy human subjects. A collecting plastic tube was introduced into the intestine 130 cm from the mouth. It was combined with 2 thinner tubes ending in the gastric antrum and duodenum. The fluid test meal (300 ml) contained polyethyleneglycol (PEG) as a marker. The nonglucose meal (NG-meal) contained 3.6% protein from skim milk powder, 6% fat from corn oil, and 5% lactose. On another occasion, the same subjects were given the same meal with 10% glucose added (G-meal). Regurgitated samples were obtained in 3 experiments with the NG-meal and in 5 with the G-meal. After the G-meals, the concentration of hydrochloric acid was 99.7 mEq/liter. The amounts of PEG decreased faster than the concentrations during the early periods after which the decrease was more parallel. After the G-meals, the gastric secretion could be followed for at least 180 min, after NG-meals for 140 min. Gastric volumes decreased more rapidly after the NG-meals than after the G-meals. No differences in the secretion rates were found between the 2 meals.

0126 KINETICS OF ATROPINE AND DIAMOX INHIBITION OF HISTAMINE-STIMULATED GASTRIC SECRETION. *(E.)* Hirschowitz, B. I.; Hutchinson, G. A.; Sachs, G. (Div. Gastroenterol., Univ. Alabama, Birmingham). *Scand. J. Gastroenterol.* 8(6):555-559, 1973.

The kinetics of atropine and acetazolamide inhibition of histamine-stimulated gastric secretion were studied in 7 mongrel dogs, each prepared with a Komarov esophagostomy and a Dragstedt gastric cannula. If, after a 16-hr fast with water allowed, there was no basal secretion, histamine was given i.v. as histamine acid phosphate in successive 45-min dose increments as follows: 2, 5, 10, 20, 50, 100, and 150 μg/kg/hr. The atropine was given into another vein at a constant rate of 10 μg/kg/hr in 11.5 ml saline/hr. The acetazolamide (50 mg/kg) was given in one slow injection 15 min before the start of the histamine infusion. Gastric juice was collected in consecutive 15-min periods. Blood samples were taken at the start and the end. The peak acid output occurs at 100 μg/kg/hr in the control study of histamine alone. With atropine, the S-shaped curve is shifted down and to the right, but maintains the same shape. With acetazolamide, the curve is substantially flattened, with far greater reduction at the higher doses and little dose-responsive increase in output. The output of pepsin was small with all 3 types of histamine experiment. In the control study, peak output occurred with 5 μg/kg/hr of histamine and then declined progressively as the dose was increased. Atropine suppressed the output more at lower doses of histamine; acetazolamide seemed to stimulate pepsin secretion somewhat.

0127 THE EFFECT OF ACTH AND CORTISONE ON GASTRIC ACID MUCOSUBSTANCES IN RATS. *(E.)* Kozlowska, K. (Inst. Med. Biol., Gdansk, Poland). *Digestion* 9(3):241-247, 1973.

The effects of ACTH and cortisone on gastric acid mucosubstances were studied in 3 groups of 160 male Wistar rats each. In one group, each animal was given 5 i.p. injections of 25 mg cortisone acetate suspension. The rats of the second group were treated with 25 mg of ACTH solution in distilled water. The control animals received only physiological saline. A significant increase in the acid mucosubstance content was observed in both the fundal and antral gastric mucosa after application of ACTH and cortisone. The mucosubstances isolated from the fundus of the control animals contained a higher amount of amino sugars and uronic acids than those from the antral mucosa. After treatment with steroid hormones, there was an increased content of amino sugars, more marked in the pyloric mucosa. The administered hormones significantly increased the content of sulfated polysaccharides in both parts of the gastric mucosa, but were more significant in the antral mucosa.

SECRETION AND METABOLISM

Pancreas

0131 INTERACTIONS BETWEEN INTRALUMINAL BILE ACIDS AND DIGESTIVE PRODUCTS ON PANCREATIC AND GALLBLADDER FUNCTION. *(E.)* Malagelada, J. R.; Go, V. L. W.; DiMagno, E. P.; Summerskill, W. H. J. (Mayo Clin., Rochester, Minn.). *J. Clin. Invest.* 52(9):2160-2165, 1973.

Interactions between bile acids (taurocholate (TC), taurochenodeoxycholate, (TCDC), or taurodeoxycholate, (TDC)) and digestive products (essential amino acids, (EAA) or monoolein, (MO)) in the lumen of the proximal small bowel, affecting pancreatic enzyme secretion and gallbladder contraction, were studied in 77 healthy male volunteers (aged 21-52 yr) by a perfusion method. Perfusion of EAA or MO caused significant increases in pancreatic enzyme output together with gallbladder contraction; MO was more potent and induced enzyme outputs comparable to the maximal response attained with intravenons cholecystokinin-pancreozymin (CCK-PZ, 0.250 U/kg/min for 60 min, i.v.). Perfusion of TC alone had no effect, but addition of 10 mM of TC, TCDC, or TDC to perfusates containing EAA, or 10 mM TC to MO, or both significantly reduced pancreatic enzyme output and prevented gallbladder contraction. Addition of 5 mM TC to EAA also produced a significant inhibitory effect. Inhibition of the stimulatory action of digestive products occurred in the jejunum as well as in the duodenum. The inhibitory action of bile acid was considered intraluminal since bile acid did not modify the effects of CCK-PZ given intravenously; and the stimulatory effect of digestive products perfused in the duodenum on pancreatic and gallbladder function was not influenced by simultaneous perfusion of bile acid in the jejunum. It is suggested that this inhibitory effect of bile acid is mediated through inhibition of CCK-PZ secretion by high intraluminal concentrations of bile acid. Inhibition of CCK-PZ secretion by bile acid may regulate pancreatic and gallbladder function during digestion by reducing pancreatic enzyme secretion and permitting the gallbladder to refill after evacuation of its contents.

0132 THE ACTION OF THE C-TERMINAL OCTAPEPTIDE OF CHOLECYSTOKININ AND RELATED PEPTIDES ON PANCREATIC EXOCRINE SECRETION. *(E.)* Nakajima, S. (Nagoya Univ. Sch. Med., Japan). *Gut* 14(8): 607-615, 1973.

Dogs were prepared with pancreatic fistulae to study the effect of the C-terminal octapeptide of cholecystokinin-pancreozymin, caerulein, and the C-terminal tetrapeptide of gastrin on pancreatic secretion of fluid, electrolyte, amylase, and protein. All the polypeptides produced a qualitatively similar pancreatic response, against background stimulation of fluid secretion with submaximal doses of secretin, causing highly significant increases in amylase, protein, calcium, and zinc concentrations. Magnesium concentration was significantly increased only when the concentration preceding the administration of the peptide was below 100 μEq/liter. Cholecystokinin-pancreozymin was 13-35 times and 20-56 times more potent than tetragastrin on weight and molar bases, resp., as a stimulant of amylase secretion. The threshold doses were largest for amylase, lower for calcium, and lowest for zinc. There was a significant linear correlation between amylase and calcium concentration, zinc and protein concentration, and magnesium and calcium concentration. Some increases were produced in secretin-induced volume flow, whereas bicarbonate, chloride, sodium, and potassium concentrations were unchanged. The direct relation between bicarbonate concentration and flow rate was limited to rates below 1.5 ml/5 min. At higher rates bicarbonate and chloride concentration reached a high and low plateau, resp., although the first 5-min sample of pancreatic juice after secretin stimulation exhibited a relatively low bicarbonate and high chloride concentration compared with its voluminous flow. Chloride and bicarbonate concentrations varied inversely; the sum of these 2 anions was constant.

0133 EFFECT OF GIH CHOLECYSTOKININ-PANCREOZYMIN ON VASOMOTOR ACTIVITY OF THE ISOLATED DOG PANCREAS. RELATIONS BETWEEN VASOMOTOR ACTIVITY AND SECRETORY RESPONSE. *(Fr.)* Vaysse, N.; Martinel, C.; Lacroix, A.; Pascal, J. P.; Ribet, A. (Purpan Hosp., Toulouse, France). *Biol. Gastroenterol. (Paris)* 6(1):33-40, 1973.

Perfusion of the isolated dog pancreas with 2.5-100 Ivy U/hr of GIH cholecystokinin-pancreozymin (CCK-PZ) produced vasodilation accompanied by a drop in vascular resistance. At doses between 2.5 and 25 Ivy U/hr a linear relation was found between the dose and the drop in vascular resistance. No increase in vasodilation occurred above 25 Ivy U/hr. When secretin (10 clinical U/hr) was added to the perfusion medium along with CCK-PZ (10 or 100 Ivy U/hr), secretin caused a significant drop in vascular resistance at the lower dose but had no appreciable effect at the higher dose. At doses of 2.5 and 10 Ivy U/hr, CCK-PZ had little or no effect on pancreatic secretion, while at doses of 25 and 100 Ivy U/hr its effect varied, probably because of contamination with secretin. The volume of pancreatic secretion obtained was always higher when arterial pressure remained constant, i.e., when arterial blood flow increased due to vasodilation, than when blood flow was maintained at its basal level. Significant increases in protein output, caused by CCK-PZ but not secretin, were not the result of an increase in the volume of pancreatic secretion. This observation suggests that vasodilation and increased blood flow potentiate the protein response to CCK-PZ stimulation.

SECRETION AND METABOLISM

Hepatobiliary Tract

0142 METABOLIC ACTIVATION OF HALOTHANE AND ITS COVALENT BINDING TO LIVER ENDOPLASMIC PROTEINS *IN VITRO*. *(E.)* Uehleke, H.; Hellmer, K. H.; Tabarelli-Poplawski, S. (Pharmacol. Inst., Univ. Tubingen, Germany). *Naunyn-Schmiedebergs Arch. Pharmacol.* 279(1):39-52, 1973.

Halothane produces a difference absorption spectrum with a maximum at 473 nm and a minimum at 408 nm in suspensions of rabbit liver microsomes reduced by dithionite or reduced nicotinamide adenine dinucleotide phosphate (NADPH). The optical affinity was in the region of 3-6x10^{-6} M for dithionite reduced microsomes. The maximal absorption with dithionite reduced microsomes for halothane (473-550 nm) was 0.017-0.019 and for carbon tetrachloride (CCL$_4$) (454-500 nm) 0.04-0.05 nmol of cytochrome P-450. The appearance of the difference absorption with halothane is faster than that with CCL$_4$. During anaerobic incubation with NADPH-reduced liver microsomes from phenobarbital pretreated rabbits, ^{14}C-labelled halothane (1mM) was covalently bound to microsomal proteins at a rate of 2 nmol/mg protein in 30 min (CCL$_4$:11 nmol/mg protein in 30 min). Reduction by dithionite was ineffective. The binding of halothane was 60% inhibited in a gas phase of air, 75% by carbon monoxide, 55% in the presence of 1 mM metyrapone, 50% by CCL$_4$, but only 20% by reduced glutathione. The binding of the radioactivity from labelled halothane and CCL$_4$ to proteins of isolated rabbit lung and kidney microsomes was proportional to cytochrome P-450 concentrations in the organ fractions. Like CCL$_4$, halothane (1 mM) inhibited several microsomal drug oxidation reactions. These results suggest that irreversible binding of halothane or its metabolite(s) to endoplasmic proteins might be connected with halothane liver damage.

0143 ADRENERGIC RECEPTORS IN RAT LIVER I. EFFECTS OF EPINEPHRINE AND ADRENERGIC BLOCKING AGENTS ON GLUCONEOGENESIS IN PERFUSED LIVER. *(E.)* Hagino, Y.; Nakashima, M. (Nagoya Univ. Sch. Med., Japan). *Jap. J. Pharmacol.* 23(4):543-551, 1973.

Gluconeogenesis from lactate in normal and hypothyroid liver from Wistar male rats was examined to clarify the adrenergic receptor mechanisms. When epinephrine (at a concentration of 1 x 10^{-6} M in the perfusate) was perfused into normal liver, the level of glucose in perfusate was elevated 2-fold. An elevation also occurred in hypothyroid livers in response to epinephrine. In the hypothyroid group, the rate of glucose production decreased to about 60% that of normal during perfusion of 20 mM lactate for 30 min. In the normal liver, addition of an α or β adrenergic blocking agent together with epinephrine did not show any significant change as compared to epinephrine alone, but, in hypothyroidism, a different metabolic response was observed with the administration of adrenergic antagonists, phentolamine or propanolol, together with epinephrine. Dibutyryl AMP (1 x 10^{-4} M) had the same effect as epinephrine on gluconeogenesis from lactate in both normal and hypothyroid livers. These data suggest that the β adrenergic receptor is important in the normal liver. The α adrenergic receptor may be important in stimulated gluconeogenesis from lactate in hypothyroidism. It is possible that AMP mediates the effect of epinephrine even in the hypothyroid state.

0144 EFFECTS OF BROMOBENZENE AND CARBON TETRACHLORIDE ON THE SYNTHESIS AND RELEASE OF PROTEINS BY PERFUSED RAT LIVER. *(E.)* Davis, D.

C.; Hashimoto, M.; Gillette, J. R. (Emory Univ. Sch. Med., Atlanta, Ga.). *Biochem. Pharmacol.* 22(16):1989-2001), 1973.

The effects of bromobenzene and carbon tetrachloride (CCL_4) on the hepatic incorporation of ^{14}C-L-leucine into protein were studied to determine the relation between liver necrosis and impairment of radiolabeled protein synthesis and release caused by these toxicants. Male rats were treated with bromobenzene or CCL_4 and 4 or 12 hr later the livers were removed and perfused *in vitro* in a recirculating perfusion apparatus.CCL_4 only slightly impaired the rate of synthesis of radiolabeled proteins (liver + serum) but markedly decreased the release of radiolabeled proteins into the serum (perfusate) at 4 hr after its administration. At 4 hr after the administration of bromobenzene, the rates of incorporation of ^{14}C-L-leucine into proteins and the release of radiolabeled proteins were not appreciably changed. At 12 hr after bromobenzene, the rate of radiolabeled protein synthesis was not altered when compared with control livers, but the release of ^{14}C-labeled proteins into the perfusate was decreased. After pretreatment of rats with phenobarbital, bromobenzene decreased the synthesis and the release of ^{14}C-labeled proteins (4 hr). β-Diethylaminoethyl diphenylpropylacetate and 3-methylcholanthrene did not alter the effect of bromobenzene on the accumulation of total radiolabeled protein synthesis, while β-diethylaminoethyl diphenylpropylacetate, but not 3-methylcholanthrene, blocked the ability of bromobenzene to decrease the release of ^{14}C-labeled proteins into serum. Since bromobenzene does not alter the rate of ^{14}C-labeled protein synthesis at 4 or 12 hr after administration, impairment of protein synthesis is probably not a primary cause of bromobenzene-induced liver necrosis. Evidence suggests that the decrease in the release of ^{14}C-labeled proteins in the perfusate is due to changes in the pattern of protein synthesis as well as to decreases in the rate of protein synthesis.

0145 MAINTENANCE IN VITRO OF FUNCTIONALLY ACTIVE ADULT HUMAN LIVER.

(E.) Sandstrom, B. Dept. Human Anat., Univ. Uppsala, Sweden). *Acta epatogastroenterol.* 20(1):19-23, 1973.

technique has been devised whereby normal adult uman liver may be maintained functionally repreentative in tissue culture. The culture medium onsists of 2 parts of balanced salt solution and 1 art of fetal calf serum. The salt solution is nriched with caseine hydrolysate, streptomycin sulate, and penicillin. The pH of the salt solution s adjusted to 7.4-7.8 with isotonic NaOH. Glucose oncentration of the medium is 270 mg%. This techique is suited for experimental studies on interediary metabolism, oxygen consumption, bile secreion, and enzyme activities. It is suggested that his will be a valuable system for studies on the ventual hepatotoxicity for man of drugs and food dditives as well as in attempts to propagate human epatitis virus.

0146 METABOLIC EFFECTS OF ETHANOL IN REGENERATING RAT LIVER.

(E.) Seshachalam, D. (Creighton Univ. Sch. Med., Omaha, Neb.). *Biochem. Med.* 7(2):235-240, 1973.

Wistar male albino rats were partially hepatectomized by removal of about 70% of the liver lobes. After sacrifice, liver slices were prepared. Ethanol (10 mM) inhibited labeled carbon dioxide formation with all substrates used in both regenerating and normal rat liver slices, but this inhibition was less pronounced with succinate and galactose in normal and regenerating liver, resp. Alcohol dehydrogenase activity in both types of tissue homogenates was approximately 8×10^{-4} U/mg protein. The yield of labeled carbon dioxide in both tissue types formed from labeled ($1-^{14}C$) glucose was larger than the amount of labeled carbon dioxide produced from ($6-^{14}C$) glucose. In normal liver, 5 mM ethanol inhibited 70% of the labeled carbon dioxide formation when ($6-^{14}C$) glucose was the substrate, but only 41% with ($1-^{14}C$) glucose. In regenerating liver, however, ethanol inhibited 24% of labeled carbon dioxide formation from ($1-^{14}C$) glucose. With acetate as substrate, carbon dioxide formation was slightly greater in normal tissue than in regenerating tissue. The slower oxidation of acetate may be due to a somewhat low rate of conversion of free acetate to acetyl coenzyme A in this tissue. Attenuation of the inhibitory action of ethanol on carbon dioxide formation from labeled galactose in regenerating liver is partly due to diversion of the galactose to the hexosemonophosphate shunt and partly to resistance of the tissue to the toxicity. In contrast to galactose oxidation, succinate oxidation appears more sensitive to ethanol toxicity in the regenerating tissue.

0147 TOXICITY OF TETRACYCLINES IN RAT-SMALL-INTESTINAL EPITHELIUM AND LIVER.

(E.) De Jonge, H. R. (Rotterdam Med. Sch., Netherlands). *Biochem. Pharmacol.* 22(21):2659-2677, 1973.

Male Wistar rats suffered from severe damage of structure and function of the small intestinal epithelium and showed excessive accumulation of fat in the liver after 3 or more days of treatment with oxytetracycline (300 mg/kg, i.m.). Several possible modes of action of this drug were studied to explain this toxicity. No direct correlation was found between the strong inhibitory effect on mitochondrial protein synthesis, leading to drastically lowered mitochondrial cytochrome levels in the rapidly dividing small intestinal epithelial cells, and a disturbance of mitochondrial energy production. No epithelial cell damage was observed after chloramphenicol treatment, producing a similar decrease of cytochrome contents. At the stage of oxytetracycline treatment in which minimal cytochrome levels were reached but still no structural damage of the epithelium was observed, the energy-stores in the epithelial cells and the rate of oxidative phosphorylation in isolated intestinal mitochondria was unaffected. When morphological alterations of the villus were clearly observed histologically, after 3-4 days, the rate of proliferation of the crypt cell population was not significantly affected, suggesting again a lack of influence on energy metabolism in the crypt cells. During short incubations of isolated villous cells, the cellular energy charge and the rate of amino acid incorporation into protein strongly decreased after anaerobiosis and addition of potassium cyanide, oligomycin, or 2,4-dinitrophenol, conditions which impair the mitochondrial energetic function. However, incubation with 100-500 μg/ml of several tetracyclines, doxycycline having the strongest effect, significantly inhibited cytoplasmic protein synthesis without affecting the rate of glycolysis and respiration or the energy charge in the epithelial cells. These observations suggest that the toxic effects of oxytetracycline are based on its interaction with cytoplasmic protein synthesis under conditions of drug accumulation in blood and tissues. After extended treatment the lowering of energy charge in liver and intestine may be secondary effects of this action, namely of fatty infiltration in the liver and structural damage of the villous epithelium, resp.

0148 INCORPORATION OF ORALLY ADMINISTERED GLUCOSE-U-^{14}C AND FRUCTOSE-U-^{14}C INTO THE TRIGLYCERIDE OF LIVER, PLASMA, AND ADIPOSE TISSUE OF RATS.

(E.) Maruhama, Y.; Macdonald, I. (Guy Hosp. Med. Sch., London, England). *Metabolism* 22(9):1205-1215, 1973.

Male Wistar rats, fasted for 5-6 hr, were given 5μCi of glucose-U-^{14}C or fructose-U-^{14}C, in 0.5 g of their respective carrier, by intragastric instillation. Sequential radioactivity in plasma carbohydrates and in the triglyceride of the liver, plasma, and adipose tissue and plasma immunoreactive insulin and free fatty acids were measured. By measuring the metabolic activity of endogenous glucose, the validity of taking the triglyceride labeling rate as the triglyceride synthesis rate was tested. Radioactivity was 2-3 times greater in the liver and plasma triglycerides after fructose than after glucose while the reverse was true for adipose tissue. The greater radioactivity in triglyceride of the liver and plasma after fructose was due to triglyceride-glycerol radioactivity. The radioactivity of both triglyceride-fatty acids and triglyceride-glycerol accounted for the greater radioactivity in adipose tissue triglyceride. Three hr after glucose, 92% of the total radioactivity in triglyceride was in adipose tissue and 8% was in the liver. However, 3 hr after fructose, 57% of the radioactivity was in adipose tissue and 42% was in the liver. It is suggested that daily repetition of such a pattern of fructose handling may lead to abnormal metabolism of endogenous triglyceride.

0149 HYCANTHONE-INDUCED HEPATIC CHANGES IN MICE INFECTED WITH SCHISTOSOMA MANSONI.

(E.) Haese, W. H.; Smith, D. L.; Bueding, E. (Sch. Med., Johns Hopkins Univ., Baltimore, Md.). *J. Pharmacol. Exp. Ther.* 186(3):430-440, 1973.

Female Swiss-Webster mice were infected with cercariae of *Schistosoma mansoni*. After 54-104 weeks, hepatic hyperplasia was observed in 29% of the animals. Cessation of egg production and elimination of the worms, brought about by the administration of the schistosomicidal drug nitrovinylfuran SQ 18,506 (ig/kg, p.o. b.i.d., for 5 days) 55 days after infection, lowered the incidence of hepatic hyperplasias. Administration of a single dose of hycanthone, another antischistosomal drug, significantly increased the incidence of hepatic hyperplasia. Furthermore, the appearance of hepatocellular carcinomas was observed in hycanthone-treated infected mice, even after the adult worms had been killed and the deposition of eggs eliminated. In uninfected mice a single dose of hycanthone produced neither hepatic hyperplasia nor hepatomas. It is concluded that the hepatic hyperplasia, induced by the deposition of schistosome eggs in the liver and enhanced by hycanthone, is a predisposing factor for a hepatocarcinogenic effect of this drug.

0150 LIVER ULTRASTRUCTURE AND RNA SYNTHESIS IN DIABETIC RATS FED ON HIGH AND NON-PROTEIN DIETS.

(E.) Stenram, U.; Wilander, E. (Dept. Pathol., Univ. Uppsala, Sweden). *Virchows Arch. (Zellpathol.)* 14(1):57-68, 1973.

Male Sprague-Dawley rats were made diabetic with streptozotocin or alloxan. After a week, the rats were fed a 25% casein or a protein-free diet. After 5 days they were given ^{3}H-cytidine (2.5 μCi, i.p.) and killed after 18 hr. Liver RNA synthesis was estimated by determining the ratio specific RNA activity/specific acid-soluble nucleotide activity, and the product of the above mentioned ratio and the RNA/DNA ratio. The protein-fed, diabetic rats showed a 175% increase in liver RNA synthesis and a decreased amount of rough-surfaced endoplasmic reticulum in the liver cell cytoplasm as compared with protein-fed, nondiabetic rats. The protein-deprived, diabetic rats showed a 40% increase in RNA synthesis as compared with protein-deprived, nondiabetic rats, but no differences were noted in liver ultrastructure. The protein-deprived, nondiabetic rats had a decreased amount of rough-surfaced endoplasmic reticulum and an 82% increased ratio, specific RNA activity/specific acid-soluble nucleotide activity, as compared with the protein-fed, nondiabetic rats. The RNA labeling profiles following gel electrophoresis were of the same shape in all groups.

0151 HEPATIC DRUG METABOLISM AND PROTEIN MALNUTRITION.

(E.) Rumack, B. H.; Holtzman, J.; Chase, H. P. (Univ. Colorado Med. Ctr., Denver). *J. Pharmacol. Exp. Ther.* 186(3):441-446, 1973.

The effect of chronic protein malnutrition on hepatic microsomal drug metabolism, specifically of the mixed function oxidases was investigated. *Macaca nemestrina* monkeys fed protein-deficient diets developed classic features of marasmic kwashiorkor with edema and weight less than 60% of controls. Total microsomal heme, phospholipids, and flavin adenine dinucleotide levels, all of which are involved in microsomal drug metabolism, were significantly reduced in malnourished animals. Malnourished monkeys had significantly lower quantities of microsomal protein as well as lower activity of cytochrome P-450 reductase. Cytochrome P-450 reductase is recognized to be the central component of the mixed function oxidases in drug hydroxylations. Because of these findings, ethylmorphine and aniline were studied *in vitro* to investigate possible alterations in their metabolism secondary to malnutrition. There were no differences in kinetic data comparing the control with the malnourished group when metabolism was expressed per mg microsomal protein or per kg body weight. Alterations observed in this study, as well as previous descriptions of altered hexobarbital sleeping time, suggest the drug dosage should be reduced in the presence of protein malnutrition.

0152 BILIARY EXCRETION OF CARDIAC GLYCOSIDES.

(E.) Russell, J. Q.; Klaassen, C. D. (Univ. Kansas Med. Ctr., Kansas City). *J. Pharmacol. Exp. Ther.* 186(3):455-462, 1973.

The rat was shown to be more resistant to the lethal properties of the glycosides, ouabain, digoxin, and digitoxin than either the rabbit or dog. The rat's relative resistance did depend on the glycoside used. The smallest difference in sensitivity occurred with digitoxin to which the rat was 9 times more resistant than the rabbit and 14 times more resistant than the dog. With digoxin, the rat was 25 times more resistant than the rabbit and 92 times more resistant than the dog. The greatest difference occurred with ouabain in which the rat was 63 times more resistant than the rabbit and 110 times more resistant than the dog. Digoxin was excreted into bile similarly by both rats and rabbits (approximately 60% in 12 hr), while dogs excreted only 1/5 that amount. With digitoxin, minor quantitative differences were observed in biliary excretion in the 3 species studied (45-70% in 12 hr). In all 3, digoxin and digitoxin were excreted against an apparent bile to plasma concentration gradient, ranging from 10 to 300. These results suggest that digoxin and digitoxin are excreted into the bile by a transport process, that no general correlation between the polarity of cardiac glycosides and their biliary excretion exists, and that the additional resistance of the rat to the lethal properties of ouabain and digoxin over that observed with digitoxin is partially due to a higher rate of excretion of these 2 glycosides into the bile.

0153 ROLE OF INFECTED BILE IN SPASM OF THE SPHINCTER OF ODDI.

(E.) Poncelet, P. R.; Thompson, A. G. (Dept. Surg., Laval Univ., Quebec, Canada). *Am. J. Surg.* 126(3):387-391, 1973.

Prolonged spasm of the sphincter of Oddi in the cat was produced by contact of infected bile with the terminal common bile duct. In 1 group of cats perfusion with conjugated bile salts and free cholate did not increase sphincteric resistance. Perfusion with free chenodeoxycholate slightly increased the common bile duct pressure. Use of free deoxycholate markedly increased sphincteric resistance, suggesting that bacterial deconjugation and dehydroxylation of bile salts are responsible for the spasm. In a second group of cats, perfusion with normal hepatic bile did not change common bile duct pressure, but perfusion with infected hepatic bile caused a definite rise in pressure of about 115%. Addition of 2% sodium cholate to normal hepatic bile increased the pressure by about 70%. Addition of sodium deoxycholate caused a 400% increase in pressure. It is suggested that the increased resistance was due to a nonspecific irritating effect of infected bile, in which free bile salts were found in large amounts. No pressure changes occurred when bacteria alone were perfused, suggesting that the bacterial factor in itself plays little if any part in sphincter spasm. A spasm of the sphincter of Oddi is a possible mechanism by which an obstructive type of jaundice or pancreatitis can develop in a gallstone patient.

0154 INDUCTION OF HEPATIC MICROSOMAL REDUCED NICOTINAMIDE ADENINE DINUCLEOTIDE PHOSPHATE-DEPENDENT PRODUCTION OF HYDROGEN PEROXIDE BY CHRONIC PRIOR TREATMENT WITH ETHANOL.

(E.) Thurman, R. G. (Johnson Res. Fdn., Univ. Pennsylvania, Philadelphia). *Mol. Pharmacol.* 9(5):670-675, 1973.

Male Holtzman rats were treated for 21-28 days with a semiliquid diet containing ethanol. This resulted in a near doubling of liver microsomal cytochrome P-450 content. At the same time, significant increases in the rate of reduced nicotinamide adenine dinucleotide diphosphate (NADPH) oxidation, "endogenous" respiration, and acetaldehyde formation from ethanol in microsomes were noted. An average increase in NADPH-dependent hydrogen peroxide formation of 45% resulted from chronic ethanol treatment, employing the decrease in scopoletin fluorescence or the formation of cytochrome peroxidase complex II as hydrogen peroxide-detecting systems. Since the rate-limiting step for ethanol oxidation in microsomes is the rate of generation of hydrogen peroxide for the peroxidatic reaction of catalase, this adaptive increase in hydrogen peroxide production due to chronic ethanol treatment most likely accounts for the enhanced ethanol oxidation via catalase-H_2O_2. The data support the hypothesis that microsomal ethanol oxidation is due to peroxidation via catalase utilizing microsomal hydrogen peroxide.

0155 CRYOTHERAPY OF IMPLANTED CANCER IN THE RAT LIVER.

(E.) Grady, E. D.; Nolan, T. R.; Crumbley, A. J.; Cheek, W. V.; Copelan, N.; Kunzler, H. C. (Nuclear Res. Ctr., Georgia Inst. Technol., Atlanta). *Oncology* 28(2):104-109, 1973.

Cryosurgery was performed on solid liver tumors in rats to investigate the effect of freezing liver cancers. Of 21 Sprague-Dawley rats with single liver implants of Walker-256 tumor, 8 were apparently cured of these cancers by cryotherapy. Liver cancer was controlled in 2 others, but these had spread of cancer to other parts of the body. There was 1 operative death, but no other serious complication from the procedure. Temperatures down to -40 C, produced repeatedly, gave better results than single or double exposures at -20 C. Treatment to -5 C is not successful, even when it is repeated.

0156 LOCALIZATION OF THE ENZYMES OF KETOGENESIS IN RAT LIVER MITOCHONDRIA.

(E.) Chapman, M. J.; Miller, L. R.; Ontko, J. A. (Oklahoma Med. Res. Fdn., Oklahoma City). *J. Cell Biol.* 58(2):284-306, 1973.

The localization of the enzymes of ketogenesis in isolated rat liver mitochondria was investigated. Mitochondrial subfractions were isolated after disruption of this subcellular organelle by hypotonic lysis in water, which permitted the ultracentrifugal separation of the soluble and membranous compartments of the mitochondrion, or by a procedure involving swelling, contraction, and ultrasonic treatment, which permitted the isolation from discontinuous sucrose gradients of subfractions rich in intermembrane space protein, outer membrane, and inner membrane-matrix particles. Invariably present were 2 membrane subfractions seen as distinct bands at the lower interface of the discontinuous gradient. The upper of the 2 bands was a highly purified preparation of outer mitochondrial membrane. From inner membrane-matrix particles after hypotonic treatment, subfractions rich in matrix and in inner membrane were isolated. The content of the various mitochondrial compartments in all subfractions was assessed from their enzymic and electron microscopic characteristics. The ketogenic activity of each subfraction was determined by its capacity to form ketone bodies from acetyl coenzyme A (CoA). This activity was markedly enhanced by dithiothreitol. These measurements of ketone body formation, together with assays of individual enzymes of the ketogenic pathway, show that thiolase, B-hydroxy-B-methylglutaryl CoA (HMGCoA) synthase, and HMGCoA cleavage enzyme are localized in the matrix of the inner membrane-matrix particles. Ketone body formation rates indicate that the HMGCoA synthase is the rate-limiting enzyme of the pathway in subfractions of high matrix content. Studies with sodium chloride indicate that a large portion of the HMGCoA synthase, which remains present in membrane subfractions derived from water-treated mitochondria, is bound by ionic interaction to component(s) of the membrane.

0157 METABOLISM OF ADRENALINE IN THE ISOLATED PERFUSED LIVER OF THE RAT.

(E.) Lightman, S. L.; Hems, D. A. (Middlesex Hosp. Med. Sch., London, England). *Biochem. Pharmacol.* 22(19): 2419-2423, 1973.

Epinephrine uptake and metabolism were studied in perfused livers of Sprague-Dawley rats. Epinephrine was rapidly removed from the perfusion medium but did not accumulate in the liver. Even after 2-hr perfusions with 10-50 µg/ml epinephrine, the concentration in the liver was only 0.1-0.3 µg/g. However, metabolites of epinephrine appeared in the liver and their concentration soon exceeded that of the epinephrine in the medium. The concentration of epinephrine metabolites was directly proportional to duration of the perfusion and epinephrine concentration in the medium. In a 30-min perfusion, 300 µg epinephrine was passed through liver; about 40-50 µg of metabolites accumulated in the liver and about 120 µg emerged in the effluent medium. The accumulation of epinephrine metabolites in liver and the removal of epinephrine from the perfusion medium were markedly reduced by the presence of corticosterone (10 µg/ml) in the medium. In this situation, there was no detectable epinephrine accumulation in liver, indicating that corticosterone inhibited the entry of the catecholamine into the liver, rather than the enzymes involved in epinephrine metabolism.

0158 S-ADENOSYLMETHIONINE: GUANIDINOACETATE N-METHYLTRANSFERASE ACTIVITIES IN LIVERS FROM RATS WITH HORMONAL DEFICIENCIES OR EXCESSES.

(E.) Carlson, M.; Van Pilsum, J. F. (Med. Sch., Univ. Minnesota, Minneapolis). *Proc. Soc. Exp. Biol. Med.* 143(4):1256-1259, 1973.

S-Adenosylmethionine: guanidinoacetate *N*-methyltransferase (GA-methyltransferase) activities were determined in livers from rats after removal of adrenals, pituitaries, gonads, or thyroids and parathyroids. Similar determinations were made in livers from intact rats given large doses of insulin, estradiol, testosterone, cortisol, thyroxine, or growth hormone. The only statistically significant differences were between the activities of livers from intact rats and the slightly lower activities of livers from rats with their thyroid and parathyroid glands removed or from intact rats given large doses of either testosterone, thyroxine, or growth hormone. Liver GA-methyltransferase activities were unaffected by replacement of either thyroxine to thyroidectomized rats, growth hormone to hypophysectomized rats, or testosterone or estradiol to castrated rats. Therefore, direct hormonal regulation of rat liver GA-methyltransferase is contraindicated. The second enzyme involved in creatine synthesis (GA-methyltransferase), therefore, differs greatly from the first enzyme (arginine: glycine transamidinase) in that transamidinase activities were reported earlier to be altered markedly by removal of certain endocrine glands or by injections of large doses of certain hormones into intact rats.

0159 ENZYMATIC AND METABOLIC STUDIES ON CARBOHYDRATE AND AMINO ACID METABOLISM IN RAT LIVER DURING ACUTE URAEMIA.

(E.) Maier, K. P.; Hoppe-Seyler, G.; Frohlich, J.; Talke, H.; Schollmeyer, P.; Gerok, W. (Dept. Internal Med., Univ. Frieburg, Germany). *Eur. J. Clin. Invest.* 3(3): 201-207, 1973.

Enzyme activities of the glycolytic, gluconeogenic, and hexose monophosphate pathways were measured in the liver of starved female albino Sprague-Dawley rats 12 and 48 hr after bilateral nephrectomy. Control experiments revealed that enzyme activities were altered because of starvation, not uremia. Alanine-aminotransferase and aspartate-amino-transferase activities were significantly elevated in rat liver 48 hr after nephrectomy when compared with sham-operated controls. Concentrations of the gluconeogenic intermediates 3-phosphoglyceric acid, pyruvate, phosphoenolpyruvate, and glucose-6-phosphate were significantly higher in the liver of uremic animals. Amino acid analysis showed only L-alanine concentration was increased. It is suggested that the inhibition of pyruvate degradation caused the elevated content of pyruvate in the liver during acute uremia. Together with the elevated pyruvate concentration the L-alanine increase could be a consequence of the equilibrium of the alanine-aminotransferase reaction; the apparent equilibrium concentration of the reaction is not changed by uremia. Increased activities of the transaminases and the elevated concentrations of the other metabolites measured might indicate that enhanced gluconeogenesis from substrates other than pyruvate occurs in the liver of nephrectomized rats.

0160 ETHANOL AND ACETALDEHYDE METABOLISM IN RAT STRAINS GENETICALLY SELECTED FOR THEIR ETHANOL PREFERENCE. *(E.)* Eriksson, C. J. P. (Res. Lab. State Alcohol Monopoly, Helsinki, Finland). *Biochem. Pharmacol.* 22(18):2283-2292, 1973.

Ethanol and acetaldehyde metabolism were studied in both sexes in rat strains genetically selected for their ethanol preference. The strains are denoted by ANA (Alko, Non-Alcohol), which prefers water to a 10% (v/v) ethanol solution, and AA (Aldo, Alcohol), which prefers the ethanol solution. Peripheral blood and freeze-stopped livers were used for the *in vivo* studies. A once-through perfusion technique was applied so that ethanol and acetaldehyde oxidation, the cytoplasmic redox state and oxygen consumption could be measured in the same liver. There was a higher rate of ethanol oxidation and oxygen consumption in female AA rats compared with the ANA strain. Female rats of both strains had more rapid ethanol oxidation and oxygen consumption compared with the respective males. The AA strain displayed a significantly lower level of acetaldehyde during ethanol oxidation than did the ANA strain. On comparison of the liver acetaldehyde concentrations with the mitochondrial reduced nicotinamide adenine dinucleotide/reduced adenine dinucleotide (NADH/NAD) ratio, calculated from the 3-hydroxybutyrate/acetoacetate ratio, strain correlations were observed in both sexes, the ANA strain, with higher acetaldehyde having a lower 3-hydroxybutyrate/acetoacetate ratio than the AA strain, with lower acetaldehyde. Strain differences in acetaldehyde oxidation must result from differences in the aldehyde dehydrogenase activity. The AA strain apparently has a higher activity, inducing more rapid oxidation of acetaldehyde, which in turn causes a greater increase in the mitochondrial NADH/NAD ratio. The higher acetaldehyde output during ethanol oxidation in the ANA strain suggests a greater inhibitory influence on the brain metabolism, a factor which could decisively affect behavior in respect of ethanol preference.

0161 EFFECTS OF PROTEIN-CALORIE MALNUTRITION ON DRUG METABOLISM IN RAT LIVER MICROSOMES. *(E.)* Anthony, L. E. (Univ. Texas Southwestern Med. Sch., Dallas). *J. Nutr.* 103(6):811-820, 1973.

The effect of protein-calorie malnutrition in young male Holtzman rats on the liver microsomal cytochrome P-450 enzyme system functional in the oxidative metabolism of many drugs and endogenous substrates was studied. *In vitro* drug metabolism (ethylmorphine *N*-demethylation) was markedly reduced with liver microsomes from rats fed a low protein diet. Upon addition of hexobarbital, a Type I substrate, hepatic microsomes from these animals showed a much less intense spectral change than microsomes from well-fed age controls. The concentration of cytochrome P-450 was reduced while cytochrome b_5 concentration, reduced nicotinamide adenine dinucleotide phosphate (NADPH)-cytochrome *c* reductase activity, and NADPH-cytochrome P-450 reductase activity were well maintained. Administration of phenobarbital, a known inducer of the hepatic cytochrome P-450 system, increased cytochrome P-450 content, NADPH-cytochrome *c* reductase activity, NADPH-cytochrome P-450 reductase activity, oxidative drug metabolism, and the magnitude of the Type I spectral change. The findings suggest that there is reduced binding of substrates to cytochrome P-450 preceeding enzymic oxidation accounting for the reduced *in vitro* drug metabolism in microsomes from rats fed low protein diets. The observation that oxidative drug metabolism is markedly reduced in young rats on diets similar in protein value to diets eaten by children with protein-calorie malnutrition suggests that humans may metabolize foreign compounds at a greatly decreased rate.

0162 THE EFFECT OF MILD HYPOTHERMIA IN CCl_4 TOXIC HEPATITIS (HISTOLOGIC AND FUNCTIONAL STUDY). *(E.)* Bartsokas, S. C.; Papadimitriou, D. G.; Papacharalampous, N. X.; Varonos, D. (Inst. Pathol. Physiol., Univ. Athens, Greece). *Acta Hepatogastroenterol.* 20(4):275-282, 1973.

Hepatic lesions were established and liver function was impaired in adult rabbits 12 hr after carbon tetrachloride (0.6 ml/kg) administration by stomach tube. At this time hypothermia of 31-32 C for 12 or more hr, with and without the rewarming of animals, resulted in an histologic protection practically analogous to the duration of hypothermia; and the liver function was preserved at nearly normal levels. Histologic findings suggest that protective action of hypothermia is exerted through some other mechanism than that of various chemical compounds used to inhibit carbon tetrachloride toxicity.

0163 IMMUNOLOGICAL ASSESSMENT OF MICE WITH CHRONIC JAUNDICE AND RUNTING INDUCED BY REOVIRUS 3. *(E.)* Walters, M. L.; Stanley, N. F.; Dawkins, R. L.; Alpers, M. P. (Dept. Microbiol., Univ. Western Australia, Perth, Australia). *Br. J. Exp. Pathol.* 54(2):329-345, 1973.

Following acute neonatal infection with reovirus 3 in mice of Prince Henry, Balb/c, and C57Bl strains, 8.7% of mice surviving to 22 days developed a syndrome of chronic jaundice and runting. In 1.6% the syndrome persisted beyond 60 days. Immune responses, both humoral and cell-mediated, of these mice with the persisting chronic syndrome were normal or enhanced. Serum immunoglobulin levels were raised. Anti-smooth muscle antibody was commonly found beyond 100 days of age and there was a low titer of hemagglutinating autoantibody; however, no evidence for an early autoaggressive pathogenesis of the syndrome was found. Neither was there evidence of persistence of infectious reovirus or reovirus antigen in chronically affected tissues. The syndrome closely resembles active chronic hepatitis in man. The initial acute infection with reovirus 3 is essential for the production of the persisting chronic disease, but neither infectious virus nor viral antigen could be detected at this stage.

0164 MORPHOMETRIC STUDY ON THE DISTRIBUTION OF LIVER NECROSIS IN EXPERIMENTAL MURINE HEPATITIS BY MHV-3 VIRUS. *(E.)*

Piccinino, F.; Sagnelli, E. (Clin. Infect. Dis., Univ. Naples, Italy). *Acta Hepatogastroenterol.* 20(4):299-302, 1973.

The distribution of necrosis in the whole liver affected by murine hepatitis caused by MHV-3 virus, used as an experimental model in the study of human viral hepatitis was studied. A precise morphometric-photographic method was used to evaluate the extent of liver necrosis in the histological sections from different liver zones. No significant statistical differences were found in necrotic damage observed, either among the 4 lobules of mouse liver, or among sections at different distances from the porta hepatis. The frequency distribution of necrosis in 130 small areas of liver tissue, selected randomly showed an approximately normal distribution and a small deviation from the mode. This regular distribution of necrotic damage observed in the liver with murine hepatitis suggests that in human viral hepatitis the histological examination of a small area of the damaged liver may be used to predict the actual extent of the necrosis in the whole liver.

0165 INFLUENCE OF ANAESTHESIA WITH VOLATILE AGENTS ON THE EQUINE LIVER. *(E.)*

Lees, P.; Mullen, P. A.; Tavernor, W. D. (Roy. Vet. Coll. Field Stn., Hatfield, England). *Br. J. Anaesth.* 45(6):570-578, 1973.

Anesthesia was induced in 6 yearling ponies with thiopentone sodium (10 mg/kg, i.v.) and maintained for 2 hrs with halothane-oxygen in the 1st series of experiments and with ether/oxygen in a 2nd series. The influence of these anesthetic procedures on liver function was assessed by several techniques. Measurements of BSP clearance and serum protein concentrations gave no indication of altered liver function in either series. Thiopentone-halothane anesthesia also for 2 hr with halothane/oxygen in the 1st series of experiments and with ether-anaesthesia was followed by slight and transient liver cell damage, indicated by rises in serum activities of liver-rich enzymes. Histopathological changes, indicative of slight liver damage, occurred in all animals but the nature of the changes was different and characteristic for each series.

0166 THE HYPOCALCEMIC EFFECT OF ETHYL ALCOHOL IN RATS AND DOGS. *(E.)*

Peng, T. C.; Cooper, C. W.; Munson, P. L. (Univ. North Carolina, Sch. Med., Chapel Hill). *Endocrinology* 91(2):586-593, 1972.

Ethyl alcohol (2-8 g/kg, p.o.) produced a rapid and sustained hypocalcemia in rats and dogs. The rapid onset (within 30 min) and the long duration (at least 5 hr) of hypocalcemia in rats after alcohol were similar to those observed with urethane. In control experiments, addition of alcohol to rat serum did not interfere with the analytical method for measurement of calcium. No changes in blood pH or total serum proteins occurred. The hypocalcemic effect of alcohol was not due to increased loss of urinary calcium, for this effect was retained after acute nephrectomy and direct measurement of urine calcium revealed that ethanol decreased rather than increased total urinary calcium during a 3-hr period after treatment. The hypocalcemic action of alcohol differed from that of thyrocalcitonin in that the hypocalcemia caused by alcohol was not associated with hypophosphatemia, and the maximum hypocalcemic effect of alcohol in rats was only 10-15% in contrast to the 30-40% fall in serum calcium which can be produced by thyrocalcitonin. The hypocalcemic effect of alcohol was evident after acute removal of the thyroid and parathyroid glands. Therefore, the effect of alcohol was not mediated by increased secretion of thyrocalcitonin or by suppression of secretion of parathyroid hormone. Experiments using ^{45}Ca showed that alcohol caused a movement of calcium out of blood and most likely, into bone tissue. The coincidence between the occurrence of hypocalcemia and of anesthesia after large doses of alcohol suggests that neural effects of alcohol and its ability to lower serum calcium may be interrelated.

0167 GROWTH HORMONE MODULATION OF LIVER DRUG METABOLIC ENZYME ACTIVITY IN THE RAT. II. SPECIFICITY OF THE HORMONE EFFECT. *(E.)*

Wilson, J. T. (Vanderbilt Univ., Med. Sch., Nashville, Tenn.). *Proc. Soc. Exp. Biol. Med.* 143(4): 978-985, 1973.

The specificity of growth hormone (GH) on liver drug metabolic enzyme activity was examined by injecting male Fischer rats s.c. with one of three hormones [GH, prolactin, or human chorionic somatomammotropin (HCS)] known to have similar structural and biological characteristics, and by treating animals with nonhormonal polypeptides (albumin or globulin) or an amino acid mixture similar in composition to the amino acid content of human GH. The liver metabolism of hexobarbital, ethylmorphine, aniline and *p*-nitrobenzoic acid (PNBA) and the rate and extent of cytochrome P-450 reduction showed a dose-dependent decrease following injection of GH. Boiling the GH reduced its effectiveness. With the exception of ethylmorphine and PNBA metabolism, prolactin did not decrease activity of this metabolic system. One dose of HCS (ZMS) slightly decreased the metabolism of hexobarbital and slightly increased that of aminopyrine. The spectrum of effects of GH on the overall rate of drug metabolism and on components of the microsomal cytochrome P-450 system could not be reproduced with the nonhormonal polypeptides or with the amino acid mixture. It is concluded that, within the dose and time periods used for this study, (injection 48 and 40 hr prior to *in vitro* assay), the decreased steady-state level of liver drug metabolism is a relatively specific action of GH in the rat.

0168 DECREASED TOXICITY OF DIMETHYLNITROSAMINE IN RATS AFTER TREATMENT WITH CARBON TETRACHLORIDE. *(E.)* Pound, A. W.; Horn, L.; Lawson, T. A. (Queensland Univ., Med. Sch., Brisbane, Australia). *Pathology* 5(3):223-242, 1973.

A nonlethal dose of carbon tetrachloride (CCl_4) that produced necrosis in the liver, followed by regeneration, protected male Sprague-Dawley rats from the toxic effects of dimethylnitrosamine (DMN) for 48-60 hr. At 42 hr when DNA synthesis was at a maximum, the LD_{50} of DMN was increased from 27.2 to 42.5 mg/kg. DMN-demethylase in the liver fell sharply by 6 hr after CCl_4, maintained a low level for 42-60 hr, and returned to normal by 72 hr. No change occurred in the level of the DMN-demethylase in the kidney. When DMN was given 42 hr after CCl_4, the acute cellular changes and necrosis usually produced were not superimposed on the lesions produced by the CCl_4, but when the interval was 60 hr, acute necrosis was again produced in the liver. On the other hand the minor degree of necrosis in the distal convoluted tubules of the kidneys produced by DMN was much increased when it was administered 42 hr after a dose of CCl_4 but not when given after 60 hr.

)169 COMPARISON OF THE CHOLERETIC PROPERTIES OF BILE ACIDS. *(E.)* Klaassen, C. D. (Univ. ansas Med. Ctr., Kansas City). *Eur. J. Pharmacol.* 3(3):270-275, 1973.

holic acid, chenodeoxycholic, and deoxycholic acid nd their taurine and glycine conjugates were comared as to their choleretic properties and ability o form micelles. All acids studied stimulated ile production in mongrel dogs at a dosage of 55 M/kg i.v. Cholic acid increased bile volume 5-fold 595 µl/kg) within 10-20 min after administration. lycocholic and taurocholic acid resulted in volume ncreases of 428 and 450 µl/kg, resp. Chenodeoxyholic acid increased bile flow 4-fold, whereas aurochenodeoxycholic produced a 3-fold increase and lycodeoxycholic acid only a 2-fold increase. Deoxyholic and taurodeoxycholic acid both increased ile flow 4-fold *versus* a 2-fold increase for glydeoxycholic acid. Thus, the glycine and taurine onjugates, with the exception of taurodeoxycholic cid, for all bile acids were less choleretic than e parent compounds. These results indicate that ere is not a good inverse correlation between the icellar properties of bile acids and their ability o increase bile flow. Either the micellar operties of bile acids are different in bile from ose reported in other experimental conditions, or e choleresis produced by the various bile acids is not due simply to the osmotic properties of the bile acids in the canaliculi. It is also possible that bile acids alter the bile salt-independent fraction of bile formation.

0170 EFFECTS OF ETHANOL ON AMINO-ACID UPTAKE AND UTILIZATION BY THE LIVER AND OTHER ORGANS OF RATS. *(E.)* Chambers, J. W.; Piccirillo, V. J. (Med. Coll. Virginia, Richmond). *Q. J. Stud. Alcohol* 34(3):707-717, 1973.

Isolated livers from male Sprague-Dawley rats were perfused with 20 ml defibrinated rat blood and 80 ml Krebs bicarbonate buffer, the perfusate containing about 100 ml glucose and 1000 U heparin. Ethanol (200 mg/100 ml perfusate) did not significantly decrease leucine uptake by the isolated perfused rat liver, but did decrease the uptake of alanine by 34.0% and the uptake of α-aminoisobutyric acid by 40%. It is suggested that an increase in the concentration of reduced nicotinamide adenine dinucleotide is responsible for the inhibition of amino-acid uptake. The fact that the addition of pyruvate or fructose to the perfusate reverses this inhibition may only represent a more rapid destruction of the alcohol. Incorporation of radioactive alanine into protein in the isolated perfused liver was inhibited 35% by ethanol. Incorporation of labeled leucine in the presence of 200 mg ethanol was significantly, though not as greatly, inhibited. Urea production by the isolated perfused rat liver was inhibited by 200 mg ethanol whether or not utilizable amino acids were added to the perfusate. It is suggested that a decrease in the conversion of amino acids to keto acids, as implied by reduced urea production, causes a decrease in gluconegenesis which may be responsible in part for the reduced glucose production. Administration of ethanol (3g/kg) to the intact rat inhibited the uptake of α-aminoisobutyric acid in the liver by 23.9%, in the gut by 50.6%, and in the kidney by 21.3%. The considerable inhibition of α-aminoisobutyric uptake into gut tissue may reflect a direct toxic effect of high concentration of alcohol as well as a reduction of uptake caused by increases in reduced nucleotide due to ethanol oxidation. These data indicate that the inhibition of uptake was related to the shift in the $NAD:NADH_2$ ratio resulting from the oxidation of ethanol.

0171 HEPATIC GALACTOSE METABOLISM AFTER SIDE-TO-SIDE PORTACAVAL SHUNT. *(E.)* Smith, G. W.; Hulbanni, S. V. (Univ. Virginia Sch. Med., Charlottesville). *J. Surg. Res.* 15(3):163-167, 1973.

Baseline studies for liver blood flow, oxygen consumption, and galactose utilization were performed in 35 mongrel dogs. In 6 others only blood flow and galactose data were obtained. In all 41 animals a side-to-side portacaval shunt was then created. After 45 min, hepatic artery and portal flows were recorded and heparinized blood samples were obtained from the hepatic artery, portal vein, hepatic vein, and inferior vena cava. These samples were analyzed for oxygen content. A galactose load of 500 mg/kg was administered directly into the portal vein and 15 min later heparinized blood samples for galactose were withdrawn from the hepatic artery, portal vein, hepatic vein, and inferior vena cava. Galactose utilization by the liver was investigated in 13 animals, on the basis of liver weight. A 62% reduction from 906 to 350 cu cm/kg/min in total liver blood flow was noted after shunt along with a drop in portal vein flow from 628 to 82 cu cm/kg/min. No compensatory increase in hepatic artery flow occurred. Hepatic oxygen consumption decreased by 27% from 26.2 to 19.1 ml/min. Galactose utilization reduced from 63.3 to 0.3 mg/min after shunt. Expressed in terms of liver weight, galactose utilization fell from 15.7 to 2.3 mg/g liver/hr. This investigation points to significant impairment of hepatic galactose metabolism by a side-to-side portacaval shunt in the dog.

0172 PLASMA AND BRAIN TRYPTOPHAN CHANGES IN EXPERIMENTAL ACUTE HEPATIC FAILURE. *(E.)* Curzon, G.; Kantamanenin, B. D.; Winch, J.; Rojas-Bueno, A.; Murray-Lyon, I. M.; Williams, R. (Inst. Neurol., London, England). *J. Neurochem.* 21(1):137-145, 1973.

Hepatic devascularization of pigs rendered them an acceptable experimental model for acute hepatic failure in man. Liver function was grossly impaired after operation and movements became incoordinated and coma ensued. Most animals died 5-1/2 to 8-1/2 hr after operation. Plasma unesterified fatty acid and free (but not total) tryptophan concentrations rose markedly after operation and correlated significantly with each other. Brain tryptophan concentration increased and correlated significantly with plasma free tryptophan concentration. Increased tryptophan was found in the 4 brain regions studied (hypothalamus, thalamus, caudate, and cortex) and was associated with raised 5-hydroxytryptamine turnover as indicated by raised 5-hydroxyindolylacetic acid concentration. The raised free tryptophan concentration in the operated animals is important since it is this fraction which is available for transport into the brain. Striking elevations of free plasma tryptophan were found in this study and also in some patients with acute hepatic failure.

0173 THE EFFECTS OF HALOTHANE ON METABOLISM AND CALCIUM UPTAKE IN MITOCHONDRIA OF THE RAT LIVER AND BRAIN. *(E.)* Rosenberg, H.; Haugaard, N. (Tufts Univ. Sch. Med., Boston, Mass.). *Anesthesiology* 39(1):44-53, 1973.

The actions of halothane on respiration of mitochondria prepared from liver and brain obtained from male Wistar rats and on the uptake of calcium by brain mitochondria were studied *in vitro*. Halothane markedly inhibited ADP-stimulated respiration of both liver and brain mitochondria. With glutamate the sensitivity to inhibition by halothane was greater than with succinate as substrate. Halothane inhibits oxidative phosphorylation and, except in some circumstances at very high concentrations, is not an uncoupling agent. In liver mitochondria halothane effectively inhibited the increases in rates of respiration produced by calcium and phosphate when glutamate was the respiratory substrate. In the presence of succinate this effect was not seen with mitochondria respiring. Halothane inhibited calcium uptake by brain mitochondria when the mitochondria were incubated in the presence of ATP, ATP plus glutamate and phosphate, and ATP plus succinate and phosphate. The inhibitory action of halothane was preceded in time by a temporary stimulation of calcium uptake with succinate as the substrate. Additional experimentation is suggested to determine whether halothane influences calcium movements in the brain *in vivo* and whether such actions of a general anesthetic are important in the production of the anesthetic state in the intact organism.

0174 THE STIMULATION OF LIPID PEROXIDATION PRODUCED BY DIMETHYLNITROSAMINE IN RAT LIVER MICROSOMES IN VITRO: THE EFFECTS OF PROMETHAZINE AND INHIBITORS OF DRUG METABOLISM, AND A COMPARISON WITH PREVIOUS STUDIES USING CARBON TETRACHLORIDE. *(E.)* Jose, P. J.; Slater, T. F. (Dept. Biochem., Univ. Brunel, Uxbridge, England). *Xenobiotica* 3(6):357-366, 1973.

Addition of dimethylnitrosamine (3 μliter) to liver microsomal suspensions prepared from female albino rats increased the rate of reduced nictotinamide adenine dinucleotide phosphate (NADPH)-linked lipid peroxidation by 11%. The stimulatory effects of dimethylnitrosamine on microsomal lipid peroxidation were decreased by inhibitors of microsomal oxidative drug metabolism, carbon monoxide (5-min. gassing), β-diethylaminoethyl-3,3-diphenylpropylacetate (100 μM), and p-chloromercuribenzoate (84 μM) and by promethazine, but were not altered by the substitution of the NADPH by an equimolar concn. of reduced nictotinamide adenine dinucleotide. Dimethylnitrosamine interacts with cytochrome P-450 as shown by the use of difference spectra, and the stimulation of lipid peroxidation probably depends upon metabolism of the dimethylnitrosamine at this site. It is suggested that the lipoperoxidative properties of dimethylnitrosamine may be due to free radical metabolites, since promethazine did not inhibit oxidative peroxidation by the compound. However, the sensitivity of any such free radical metabolites to the scavenging actions of promethazine is less than that of metabolites of carbon tetrachloride.

0175 COMPARISON OF ACTIVITIES OF DRUG-METABOLIZING ENZYMES IN HUMAN FETAL AND ADULT LIVERS. *(E.)* Pelkonen, O.; Kaltiala, M. H.; Larmi, T. K. I.; Karki, N. T. (Dept. Pharmocol., Univ. Oulu, Finland). *Clin. Pharmacol. Ther.* 14(5):840-846, 1973.

The *in vitro* capacity of human fetal liver to metabolize 3,4-benzypyrene, (10 mg adult and 50 mg fetal) aniline (50 mg), aminopyrine (50 mg), and hexobarbital (50 and 100 mg) was lower than that of human adult liver from patients with uncomplicated cholelithiasis. Fetal liver drug-metabolizing capacity, expressed as percentages of adult values, was 2.4, 27.8, 32.0, and 36.1% resp., for the following substrates; benzypyrine hydroxylase, aminopyrine demethylase, aniline hydroxylase, and hexobarbital oxidase. Cytochrome P-450 content and nicotinamide adenine dinucleotide phosphate cytochrome c reductase activity in fetal liver microsomes also reflected the lower drug-metabolizing activity, being 27.4 and 49.2%, resp., of adult values. Microsomal protein content was about 26 mg/g wet weight in fetal liver and about 35 mg/g in adult liver. Recovery of microsomes was 40% to 60% in both fetal and adult livers. All parameters studied exhibited 3- to 11-fold variation. Thus the *in vitro* ability of the human fetal liver to metabolize foreign compounds seems lower than that of the human adult liver. However, if drug metabolite transfer through the placenta is slower than the transfer of the original drug, there may be an accumulation of the metabolites on the fetal side.

0176 EFFECTS OF VARIOUS CENTRALLY ACTIVE DRUGS ON HEPATIC MICROSOMAL ENZYMES: A COMPARATIVE STUDY. *(E.)* Valerino, D. M.; Vesell, E. S.; Johnson, A. L.; Aurori, K. C. (Milton S. Hershey Med. Ctr., Hershey, Pa.). *Drug Metab. Disposition.* 1(5):669-678, 1973.

The extent to which 6 centrally active drugs stimulated hepatic microsomal enzymes of mature male Sprague-Dawley rats was compared. Of the 3 parameters examined, diphenylhydantoin (50 and 100 mg/kg, i.p.) enhanced only ethylmorphine N-demethylase activity and cytochrome P-450 content, whereas the other 5 drugs stimulated aniline hydroxylase activity as well. By measuring changes in these microsomal systems after 3, 7, and 14 of drug administration, the stimulatory capacities of the 6 drugs were determined and compared. The stimulatory capacity of each drug was dose related and varied considerably in the temporal pattern exhibited. Near maximal stimulation of all 3 parameters occurred after 3 daily i.p. injections of phenobarbital (25 and 50 mg/kg), whereas 8 and 16 mg/kg chlorpromazine 40 mg/kg. diazepam 220 mg/kg meprobamate, and diphenylhydantoin produced maximal stimulatory responses only after 7-14 daily injections. Daily administration of high doses of diphenylhydantoin or ethanol decreased the activity or content of at least 1 of the 3 microsomal systems under investigation. On a molar basis, phenobarbital was the most potent stimulatory agent after 3 daily injections; at this time the other 5 drugs were generally similar to one another. In the doses employed in this study, only phenobarbital produced more than 2-fold stimulation of all 3 microsomal parameters. After 7 days of administration, 50 and 100 mg/kg diphenylhydantoin elevated ethylmorphine N-demethylase activity 240% above control values.

0177 EFFECT OF D-PENICILLAMINE ON THE GALACTOSAMINE HEPATITIS MODEL IN RATS. *(Ger.)* Habersang, S.; Kozlik, V.; Leuschner, F.; von Schlichtegroll, A. (Chemiewerk Homburg, Frankfurt/Main, Germany). *Arzneim. Forsch.* 23(1):56-57, 1973.

Liver damage was inhibited or alleviated in Sprague-Dawley rats by administering D-penicillamine (50, 100, or 200 mg/kg/day p.o.) for 21 days before injection of galactosamine hydrochloride (6 injections of 250 mg/kg i.p. each) in a 32-hr period. Rats treated with D-penicillamine had significantly higher liver contents of uridine phosphates and significantly lower SGOT, SGPT, and bilirubin values than rats given galactosamine alone. D-penicillamine had a similar effect on lipid metabolism: in doses of 100 and 200 mg/kg/day, it significantly reduced total and free serum cholesterol and total serum lipid levels in a dose-dependent manner. No changes occurred in triglycerides, total lipids, or phosphatides in the liver.

0178 INFLUENCE OF DIET ON METABOLISM AND EXCRETION OF BROMOSULPHTHALEIN SODIUM. *(E.)* Ware, A. T.; Combes, B. (Univ. Texas Southwestern Med. Sch., Dallas). *Am. J. Physiol.* 225(6):1260-1264, 1973.

The effect of a 48-hr fast on the hepatic components of the BSP conjugating system was studied in female Sprague-Dawley rats and contrasted with previously observed changes induced in animals fed a protein-free diet (PF) for 48 hr. Fasting causes a 25% fall in hepatic glutathione (GSH) content compared to a 70% decrease in PF rats. BSP conjugating enzyme activity fell by about 20% with both dietary regimens. *In vivo* studies demonstrated: normal BSP excretion in both groups following conjugated BSP infusion; and a fall in maximal BSP excretion (BSP T_m) in PF animals given free BSP. This decrease in BSP T_m is due to decreased excretion of conjugated BSP, despite hepatic levels of conjugated BSP equal to those attained during infusion with conjugated BSP, and associated with a decrease in the proportion of conjugated BSP relative to free BSP in the liver. The presence of free BSP in the liver inhibits the excretion of conjugated BSP.

0179 ω-HYDROXYLATION OF STEROID SIDE-CHAIN IN BIOSYNTHESIS OF BILE ACIDS. *(E.)* Bjorkhem, I.; Gustafsson, J. (Dept. Chem., Karolinska Inst., Stockholm, Sweden). *Eur. J. Biochem.* 36(1):201-212, 1973.

ω-Hydroxylation (26-hydroxylation) of various C_{27}-steroids by the microsomal and mitochondrial fraction was studied. Assay conditions for the microsomal 26-hydroxylation were determined with 5β-cholestane-3α,7α-diol as substrate. Reduced nicotinamide adenine dinucleotide phosphate (NADPH) was the required cofactor. Reduced nicotinamide adenine dinucleotide (NADH) stimulated the hydroxylation at suboptimal concentrations of NADPH. Carbon monoxide inhibited the microsomal 26-hydroxylation about 85%. Treatment with phenobarbital slowed the reaction rate from 1.83 to 0.40 mmol/mg protein/20 min, starvation or biliary drainage had no significant effect. The rates of microsomal 26-hydroxylation of different C_{27}-steroids expressed in μmol/mg protein/20 min were cholesterol, <0.1; 5-cholestene-3β,7α-diol, <0.1 7α-hydroxy-4-cholestene-3-one, 0.3; 7α,12α-dihydroxy-4-cholesten-3-one, 0.9; 5β-cholestane-3α,7α-diol, 1.8; 5β-cholestane-3α,7α,12α-triol, 2.7. Assay conditions for the mitochondrial 26-hydroxylation were determined with cholesterol and 5β-cholestane-3α,7α-diol as substrates. The rate of reaction was faster with an NADPH-generating system than with NADPH. Carbon monoxide inhibited the mitochondrial 26-hydroxylation about 95%. Biliary drainage inhibited the reaction whereas starvation or treatment with phenobarbital stimulated the reaction, but not significantly. The rates of mitochondrial 26-hydroxylation of different C_{27}-steroids expressed in nmol/mg protein/20 min were: cholesterol, 0.3; 5-cholestene-3β,7α-diol, 0.9; 7α-hydroxy-4-cholesten-3-one, 1.7; 7α,12α-dihydroxy-4-cholesten-3-one, 0.9; 5β-cholestane-3α,7α-diol, 0.9; 5β-cholestane-3α,7α,12α-triol, 2.0. The results are consistent with previously postulated pathways concerning biosynthesis of cholic acid and chenodeoxycholic acid in which 5β-cholestane-3α,7α,12α-triol and 5β-cholestane-3α,7α-biol, resp., are the main substrates for the 26-hydroxylase. It is suggested that pathways involving intermediary formation of 7α,26-dihydroxy-4-cholesten-3-one and 7α,12α,26-trihydroxy-4-cholesten-3-one are also of importance in the biosynthesis of bile acids.

0180 METABOLIC CONTROLS IN PRECANCEROUS LIVER. V. LOSS OF CONTROL OF CHOLESTEROL SYNTHESIS DURING FEEDING OF THE HEPATOCARCINOGEN 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE. *(E.)* Horton, B. J.; Horton, J. D.; Sabine, J. R. (Waite Agric. Res. Inst., Adelaide, Australia). *Eur. J. Cancer* 9(8):573-576, 1973.

Dietary control of cholesterol synthesis in the livers of 50 male Hooded-Wistar rats was examined during the feeding of 3'-methyl-4-dimethyl-aminoazobenzene. Repeated tests were performed on the same animals. Synthesis was measured as plasma levels of 7-dehydrocholesterol following a single dose of trans-1, 4-bis (2-chlorobenzylaminomethyl) cyclohexane dihydrochloride, a drug which inhibits the conversion of 7-dehydrocholesterol to cholesterol. The 3'-methyl-4-dimethyl-aminoazobenzene feeding caused a small, but usually statistically significant, loss of dietary feedback control of hepatic cholesterol synthesis, evident after only 1 week on the carcinogenic diet. However, control rapidly returned to normal as soon as the carcinogen treatment was discontinued. The loss of control was similar to that reported for 3 other hepatocarcinogens, aflatoxin, N-2-fluorenylacetamide and ethionine.

0181 BILIARY EXCRETION OF NICOTINAMIDE RIBOSIDE. A POSSIBLE ROLE IN THE REGULATION OF HEPATIC PYRIDINE NUCLEOTIDE DYNAMICS. *(E.)* MacGregor, J. T.; Burkhalter, A. (Dept. Pharmacol., Univ. California, San Francisco). *Biochem. Pharmacol.* 22(21):2645-2658, 1973.

Female Sprague-Dawley rats fed approximately 5 mg/day/kg of ^{14}C-nicotinic acid excreted 10% of the daily ingested label in bile and 57% in urine. About 2/3 of the label in bile was present as nicotinamide riboside. Chemical analysis of nicotinamide riboside indicated that about 7 μmoles/day/kg were excreted into bile. Chemical and radiochemical analyses both indicated that biliary nicotinamide riboside excretion may account for a major fraction of the hepatic pyridine nucleotide turnover. Nicotinamide riboside was not detected in urine, while 1-methylnicotinamide was present in urine but not in bile. Of the daily dietary intake, 6.7% was excreted in bile as nicotinamide riboside while 19.6% was excreted in urine as 1-methylnicotinamide. After administration of nicotinic acid (150 mg/kg, i.p.) or nicotinamide (500 mg/kg, i.p.), the hepatic nicotinamide adenine dinucleotide (NAD$^+$) content increased 2 to 4-fold, accompanied by a marked increase in the turnover of this newly formed NAD$^+$. The biliary excretion of nicotinamide riboside increases up to 10 times during this period of increased hepatic NAD$^+$ turnover. The nicotinamide riboside excretion appeared related to the elevation of NAD$^+$ and was independent of whether nicotinic acid or nicotinamide was used as the precursor. Comparison of the biliary nicotinamide riboside excretion with published values for the urinary excretion of NAD$^+$ metabolites during a similar hepatic NAD$^+$ increase indicates that the biliary route may be a major pathway for hepatic NAD$^+$ metabolite elimination. 1-Methylnicotinamide was not found in bile unless very large i.v. doses were given to animals with ligated renal pedicles. It is suggested that the biliary system is important in pyridine nucleotide dynamics and that biliary nicotinamide riboside excretion may be related to the secretion of other organic cations into bile.

0182 THE EFFECT OF COPPER LOADING ON THE DISTRIBUTION OF COPPER IN RAT LIVER CYTOSOL. *(E.)* Bloomer, L. C.; Sourkes, T. L. (Dept. Psychiatry, McGill Univ., Montreal, Canada). *Biochem. Med.* 8(1):78-91, 1973.

Male Sprague-Dawley rats were given i.p. injections of copper (2.5 mg Cu^{2}/kg/day as copper sulfate in 0.9% NaCl) for 1-10 days. Copper in the total liver and cytosol were measured. In related experiments, copper (50 μg/g liver was added to the sucrose used to homogenize control livers. Copper accumulated predominantly in the particulate fractions of the liver after i.p. injection, whereas 46% of the copper added *in vitro* was found in the cytosol. The distribution of copper within the cytosol was different when copper was added *in vivo* or *in vitro*. In the former case, as much as 60% of the copper co-chromatographed with proteins of molecular weight 11,500-14,000 (C-peak proteins), in the latter case the added copper was bound to high molecular-weight proteins (>100,000). Copper loading favored the binding of copper to C-peak proteins in rat liver cytosol. At termination of copper injections the copper in the C-peak decreased exponentially. The protein content of copper-containing fractions was determined. A protein was identified which may act as a transport protein and whose copper content depends on the degree of copper balance in the rat; i.e., it varies with the total liver copper. Preliminary experiments suggest that copper may be bound to the protein in the cuprous form.

0183 MODIFICATIONS OF THE BILIARY EXCRETION OF BILIRUBIN GLUCURONIDE IN RATS WITH PORTACAVAL SHUNT: THE ROLE OF UDP-GLUCURONYL TRANSFERASE. *(E.)* Okolicsanyi, L.; Vassanelli, P.; Scremin, S.; Stella, G. D. (Pathol. Inst. Special Med., Padua, Italy). *Biomedicine* 19(6):253-256, 1973.

Bilirubin metabolism was investigated in 36 Sprague-Dawley rats 20 days after end-to-side protacaval anastomosis. An observed 10 min. delay in the excretion of injected pigment appeared to be related to decreased liver glucuronyltransferase activity caused by the portacaval shunt. Sodium phenobarbital (80 mg/kg, i.p.) administered days 17, 18 and 19 after intervention in 5 rats stimulated glucuronyltransferase activity, which reached the same values as in normal rats. Bilirubin excretion also returned to normal. Conjugated bilirubin injection gave an excretion curve similar to that observed in phenobarbital-pretreated rats. These results indicate that under the experimental conditions the decrease of glucuronyltransferase activity is important in determining the changes of bilirubin metabolism.

0184 FATTY ACID ACTIVATION AND ACYL TRANSFER IN RAT LIVER DURING CLOFIBRATE FEEDING. *(E.)* Daae, L. N.; Aas, M. (Inst. Clin. Biochem., Univ. Oslo, Norway). *Atherosclerosis* 17(3):389-400, 1973.

SECRETION AND METABOLISM

Intestine

0193 BILE SALT METABOLISM AND THE COLON. *(E.)* Morris, J. S.; Low-Beer, T. S.; Heaton, K. W. (Roy. Free Hosp., London, England). *Scand. J. Gastroenterol.* 8(5):425-431, 1973.

The fate of ^{14}C-labeled sodium taurocholate in duodenal samples from 6 subjects (3 males and 3 females, aged 32-63 yr) with an ileostomy was studied. The diagnoses included ulcerative colitis in 5 cases, and intestinal polyposis in 1. Less radioactivity appeared in the form of deoxycholate conjugates in subjects with an ileostomy than in controls. The overall rate of loss of radioactivity was normal in those with an ileostomy, indicating that no malabsorption of bile salts occurred in the absence of a colon. In most ileostomy subjects, however, there was rapid deconjugation of bile salts. In these 2 groups of subjects and in 3 patients with an ileo-rectal anastomosis the relative proportions of glycocholate, glycochenodeoxycholate, and glycodeoxycholate were measured in duodenal aspirates. In subjects with an ileostomy little or no glycodeoxycholate was present, but in those with an ileo-rectal anastomosis glycodeoxycholate levels approached the normal range. These findings suggest that deoxycholate is formed in the colon and that bile salt recirculation is not impaired in the absence of the colon.

0194 HORMONAL CONTROL OF INTESTINAL ALKALINE PHOSPHATASE SECRETION IN THE DOG. *(E.)* Dyck, W. P.; Hall, F. F.; Ratliff, C. R. (Scott White Clin., Temple, Tex.). *Gastroenterology* 65(3):445-450, 1973.

Intestinal alkaline phosphatase was released into the perfused small intestinal lumen of the dog upon injection of secretin (4 U/kg, i.v.) and cholecystokinin (0.5-5 U/kg, i.v.). Since bile and pancreatic juice were excluded from the perfusion solution, a direct hormonal effect on the intestinal mucosa is considered responsible for the enzyme release. A simultaneous increase in the alkaline phosphatase activity of both mucosal tissue and perfusion solution after hormonal stimulation suggests a direct potentiaion of the secretory process rather than a simple washout phenomenon or increased enzyme extrusion through the mechanical effects of muscular contraction of the gut wall. The effect exerted by secretin on enzyme release was not as pronounced as that of cholecystokinin. Isoenzyme characterization studies, based on different susceptibilities to urea and L-phenylalanine inhibition and to heat inactivation, indicate similarities between canine and human intestinal alkaline phosphatase, and suggest that the mucosal and perfusion solution enzymes are identical.

0195 EFFECT OF IONIZING RADIATION ON FETUS. ACTIVITY OF SOME HYDROLYTIC ENZYMES IN THE SMALL INTESTINE OF RATS IRRADIATED DURING PRENATAL DEVELOPMENT. *(E.)* Trojczuk, D.; Owdiejczuk, R. (Med. Acad., Poznan, Poland). *Acta Physiol. Pol.* 23(4):711-718, 1973.

The effect of irradiation on the intestinal activity of glycolytic enzymes in the early period of postnatal development was investigated. Wistar rats were irradiated on the 18th day of uterine life with the dose of 186 rad. The activity of 2 glycolytic enzymes, β-fructofuranosidase and β-galactosidase, and 1 proteolytic enzyme, glycyl-leucine dipeptidase, was determined in the small intestine on the 1st, 10th, 20th, 25th, and 50th day of postnatal life. The total activity of enzymes in the intestinal homogenate and on the surface of the intestine was determined. Proteins were assessed simultaneously, and the enzyme activity was recalculated per 1 mg of protein or 100 mg of fresh tissue. The results show that irradiation of the rat fetus on the 18th day of embryonal life increased the β-fructofuranosidase, β-galactosidase, and glycyl-leucine dipeptidase activities in the small intestine epithelium. These disturbances began in the early postembryonic life and were of transient character. Normalization occurred in parallel with maturation of neurohormonal system.

0196 STARCH HYDROLYSIS IN MAN: AN INTRALUMINAL PROCESS NOT REQUIRING MEMBRANE DIGESTION. *(E.)* Fogel, M. R.; Gray, G. M. (Stanford Univ. Sch. Med., Calif.). *J. Appl. Physiol.* 35(2):263-267, 1973.

The relative contribution to starch hydrolysis of intraluminal amylase *versus* amylase adsorbed to the microvillous membrane was studied. Jejunal perfusion and test meal experiments were performed in 9 normal human subjects as well as in 5 patients (aged 33-54 yr) with exocrine pancreatic insufficiency, as these patients are generally assumed to have defective starch hydrolysis. Normal controls were able to hydrolyze 7.3 g of a 9.0 g infused starch load/hr to an average molecular weight of 610 g, whereas the patients could only hydrolyze 4.3 g/hr to an average molecular weight of 1836 g. The hydrolytic capacity of the intraluminal contents in both groups was more than adequate to explain the observed starch hydrolytic rate despite the fact that the patients had only 10% of the hydrolytic capacity of the control subjects. Starch given in a starch-protein-fat test meal was hydrolyzed rapidly enough to suggest that patients with exocrine pancreatic insufficiency should utilize starch-containing foods as a source of calories. In response to the test meal, the amount of amylase present in normal subject ranged from 1400-7000 U/ml, whereas in pancreatic insufficiency patients the range was 18-300 U/ml. Since the available intraluminal hydrolytic capacity is greatly in excess of that needed to account for the observed rates of starch hydrolysis in man, membrane digestion of starch is probably of secondary importance.

0197 IMMUNOGLOBULINS IN THE INTESTINAL CONTENT OF THE HUMAN FETUS WITH SPECIAL REFERENCE TO IgA. *(E.)* Petit, J. C.; Galinha, A.; Salomon, J. C. (Inst. Res. Sci. Cancer, Villejuif, France). *Eur. J. Immunol.* 3(6):373-375, 1973.

The gut walls and gut contents of 27 fetuses were analyzed for the presence of immunoglobulins. Secretory IgA was detected in 16 samples, IgM in 22 samples, IgG in 25 samples, while all 3 classes were detected in 16 samples. No IgA was found in the meconia of neonates, suggesting a transient synthesis during fetal life which is interrupted during the weeks before birth, followed by a reinduction of synthesis possibly related to stimulation by antigens in milk and intestinal flora. The assumption is made that the fetal environment is antigen-free and that early immunoglobulin production may be independent of antigenic stimulation. It is suggested that the immunoglobulins have an intrinsic fetal origin at about the 12th week of gestation, coinciding with the first step in the development of lymphoid tissues. These immunoglobulins are either evidence of an auto-immune response or they are devoid of specific activity. These observations on early immunoglobulin production in fetal gut support the theory that intestinal lymphoid tissue is a first-level lymphoid organ.

0198 QUANTITATIVE DISTRIBUTION OF SOME ENZYMES ALONG THE VILLI AND CRYPTS OF HUMAN SMALL INTESTINE. *(E.)*

Nordstrom, C.; Dahlqvist, A. (Dept. Nutr., Chem. Ctr., Lund, Sweden). *Scand. J. Gastroenterol.* 8(5):407-416, 1973.

A microdissection technique has been used to study the quantitative distribution of sucrase, maltase, isomaltase, trehalase, lactase (also in a patient with hypolactasia), leucyl naphthylamidase, alkaline and acid phosphatase, acid and hetero β-galactosidase, β-glucuronidase and thymidine kinase, along the villi and crypts of the human small intestine. The distribution patterns show how different enzymic properties appear and change quantitatively with age and stage of differentiation of the epithelial cells. Digestive enzymes occur almost exclusively along the villi with highest activities in the mid-villi or apical halves of the villi. Interesting differences in distribution patterns are seen within the villi. Acid phosphatase and acid β-galactosidase have a similar rather flat distribution from the crypts and to the tips of the villi, however, the activity of β-glucuronidase is decreased somewhat along the villi compared with the activity in the crypts. Lysosomal enzyme activities therefore are not confined to a special differentiative phase or age of the epithelial cells.

0199 GLUCAGON-INDUCED INCREASE OF ENTEROKINASE ACTIVITY IN HUMAN DUODENAL MUCOSA. *(E.)*

Rutgeerts, L.; Tytgat, G.; Eggermont, E. (Dept. Pediatr., Univ. Louvain, Belgium). *Digestion* 8(5):389-395, 1973.

Enterokinase, alkaline phosphatase, and sucrase were measured in duodenal mucosa of 5 normal volunteers, 1 patient with complete extrahepatic biliary and pancreatic duct obstruction, and 1 patient with active celiac disease before and after i.v. injection of glucagon (1 mg). A significant net increase in mucosal enterokinase, but not in alkaline phosphatase or sucrase, was observed during the 15-min period following the injection of glucagon. Following i.v. administration of alanine (100 mg/kg), a known stimulator of the endogenous secretion of glucagon, a similar rise in mucosal enterokinase was observed.

0200 LACTASE-PHLORIZIN HYDROLASE COMPLEX FROM MONKEY SMALL INTESTINE: STIMULATION OF HLORIZIN HYDROLASE ACTIVITY BY ORGANIC ACIDS. *(E.)*

amaswamy, S.; Radhakrishnan, A. N. (Christian ed. Coll. Hosp., Tamil Nadu, India). *Biochem. iophys. Res. Comm.* 54(1):197-204, 1973.

purified lactase-phlorizin hydrolase complex from onkey small intestine showed a new phlorizin hydroase activity at pH 3.3 in the presence of certain organic acids in addition to the normal activity at optimum pH 5.4. The highest stimulation (10- to 15-fold) was obtained with 20 mM tartaric acid followed by 10 mM fumaric, citric, *cis*-aconitic, *iso*-citric, and ascorbic acids. Higher concentrations of citric acid inhibited lactase activity at pH 3.3 but not at pH 5.4. Tartaric acid-stimulated phlorizin hydrolase activity was inhibited by a number of organic acids that had no effect on the unstimulated enzyme (α-oxoglutaric, succinic, malic, malonic, formic, glutamic, and aspartic acids). Pyruvic acid inhibited both stimulated and unstimulated activity. Sulfate and chloride ions were potent inhibitors of tartaric acid-stimulated enzyme activity.

0201 GOBLET CELL MUCIN OF RAT SMALL INTESTINE. CHEMICAL AND PHYSICAL CHARACTERIZATION.

(E.) Forstner, J. F.; Jabbal, I.; Forstner, G. G. (Toronto Western Hosp., Canada). *Can. J. Biochem.* 51(8):1154-1166, 1973.

Rat intestinal goblet cell mucin was characterized by chemical and physical methods. It is a flexible negatively charged macromolecule with molecular weight of 2.0 X 10^6, intrinsic viscosity of 15.3 dl/g, and axial ratio of 225:1. Its composition is protein 12%, total hexose 23%, hexosamine 22.4%, sialic acid 10%, fucose 6.6%, and sulfate <1% of the dry weight. It contains approximately 34 disulfide bonds/molecule. Like most mucin glycoproteins it was rich in serine, threonine, and proline (45.5 mol%) and poor in hydrophobic and sulfur containing amino acids. Acrylamide disc gel electrophoresis and analytic ultracentrifugation identified 1 major and 2 minor components. The components represented different molecular weight species of goblet cell mucin. No evidence of subunit structure was obtained by a variety of techniques, including the disruption of ionic, hydrophobic, and disulfide bonds by detergents, denaturants, or reducing agents.

0202 STUDIES ON THE QUANTITATION OF IMMUNOGLOBULIN IN HUMAN INTESTINAL SECRETIONS.

(E.) Samson, R. R.; McClelland, Shearman, D. J. C. (Univ. Dept. Therapeutics, Edinburgh, Scotland). *Gut* 14(8):616-626, 1973.

Studies on immunoglobulin measurement in intestinal secretion by the radial immunodiffusion method were made which show the effects of proteolytic digestion, IgA molecular size, and sampling and storage conditions on experimental results. Because of the presence of monomeric IgA in addition to secretory IgA, there is no satisfactory standard for IgA in gastrointestinal secretions, and only semi-quantitative results can be given. With radial immunodiffusion, IgG and IgM when subjected to tryptic digestion, and IgA when subjected to peptic digestion, may be overestimated because of the presence of fragments of immunoglobulins. In addition, pepsin rapidly destroys IgM and IgG. Both IgM and IgG are unstable in storage. The findings suggest that immunoglobulin concentration measurements in small intestinal aspirates should be interpreted with caution. These problems are also relevant to the detection of specific antibodies in gastrointestinal secretions.

0203 THE EFFECTS OF OXYGEN ON INTESTINAL CRYPT SURVIVAL IN COBALT-60-IRRADIATED MICE.

(E.) Sigdestad, C. P.; Hagemann, R. F.; Scott, R. M. (Sch. Med., Univ. Louisville, Ky.). *Radiat. Res.* 54(1):102-109, 1973.

Intestinal crypt survival was studied in male Ha/ICR mice exposed to gamma radiation in air, 100% normobaric oxygen, 100% hyperbaric oxygen (30 psi), and 6% normobaric oxygen. Exposures ranged from 900-2000 R at 47 R/min. There was no significant difference in the D_o for air, 100% oxygen, or oxygen at 30 psi. All fell between 377 and 380 R. Mice irradiated in 6% oxygen had a D_o of 529 R. The DMF (ratio of D_o in 6% oxygen to D_o in oxygen) was 1.4. The lack of difference in air and oxygen suggests that the highly vascularized (oxygenated) gut is maximally sensitive. At 3 days total cellularity increased after lower exposure to 120-150% of control levels and fell to less than control levels at doses greater than 1000 R. Hypoxia reduced the sensitivity, which required 1400 R to reduce cellularity to control levels. The compensatory response in crypt cellularity was greater, reaching values of 300% of control levels. These values also fell to near control levels with higher exposures. Crypt cellularity remained high (200%) in hypoxic mice for all doses tested. It peaked at 1700 R and reached 170% of control at 7kR. $LD_{50(5)}$ were 1413 R (air), 1356 R (oxygen), 1382 R (30 psi oxygen), and 2241 R (6% O_2). Corresponding levels of crypt survival were 13-38 in all cases.

0204 REGULATION OF TRIGLYCERIDE BIOSYNTHESIS IN ADIPOSE AND INTESTINAL TISSUE.

(E.) Polheim, D.; David, J. S. K.; Schultz, F. M.; Wylie, M. B.; Johnston, J. M. (Univ. Texas Southwestern Med. Sch., Dallas). *J. Lipid Res.* 14(4):415-421, 1973.

The synthesis of phosphatidic acid and di- and triglycerides *via* the glycerol-3-phosphate pathway is markedly inhibited by 2-monooleyl ether in microsomal and whole cell preparations obtained from adipose and intestinal tissue of golden hamsters. Monoglycerides are also inhibitors under conditions in which their hydrolysis is minimized. A correlation between inhibition by, and hydrolysis of, monoglycerides has been demonstrated. 2-Monooleyl ether is the most effective inhibitor of the several mono- and di-ethers and esters studied. The specificity of the inhibition of glycerol-3-phosphate acylation by 2-monoethers or 2-monoesters has been demonstrated because microsomal reduced nicotinamide adenine dinucleotide- and reduced nicotinamide adenine dinucleotide phosphate-cytochrome *c* reductase activities were not significantly inhibited. In intestinal mucosa the monoglyceride pathway is the major one for triglyceride biosynthesis. Added monoglycerides serve not only as additional substrate for the biosynthesis, but also inhibit synthesis *via* the glycerol-3-phosphate sequence. When intracellular monoglycerides are scarce, the synthesis shifts to the glycerol-3-phosphate route due to lessened inhibition. Thus these studies indicate that biosynthesis of triglycerides proceedes via the most efficient mechanism based on availability of substrate.

0205 RELEASE OF SEROTONIN FROM THE SMALL INTESTINE FOLLOWING HYPOTENSION IN THE CAT.

(E.) Fara, J.; Haglund, U. (Hlth. Sci. Ctr., State Univ. New York, Stony Brook). *Eur. Surg. Res.* 5(2):152-161, 1973.

Systemic hypotension was created in 14 cats by bleeding 20 to 35% of their blood from the femoral artery cannula. Local intestinal hypotension was created by placing an adjustable clamp around the superior mesenteric artery and adjusting the arterial inflow pressure to the intestine to 25-30 mm Hg for 2.5 to 3 hr, during continuous splanchnic nerve stimulation. To detect the presence of vasoactive substances, blood plasma from the animals was tested by isolated cat vascular smooth muscle, rat uterus bioassay, or direct biochemical determination of serotonin levels. The vascular smooth muscle assay revealed vasoactive properties of the plasma and pharmacological blocking studies indicated that this vasoactivity was due mainly to the presence of serotonin. This was confirmed in rat uterus bioassays and in biochemical assays in which similar high serotonin levels were demonstrated whether local intestinal or systemic hypotension had been induced, suggesting that serotonin is mainly released from the intestine. It is suggested that this intestinal serotonin release may be related to the general cardiovascular derangement seen after intestinal hypotension and hemorrhagic shock.

0206 THE ACTION OF DIBUTYRYL CYCLIC GMP (N^2-2'-O-DIBUTYRYL CYCLIC GUANOSINE-3', 5'-MONOPHOSPHATE) ON THE ILEUM OF GUINEA PIG.

(E.) Takayanagi, I.; Takagi, K. (Fac. Pharm. Sci., Univ. Tokyo, Japan). *Jap. J. Pharmacol.* 23(4):573-575, 1973.

Part of the ileum from male guinea pigs was placed in a modified Locke-Ringer solution and tested for its response to drugs. Dibutyryl cyclic guanosine-3', 5'-monophosphate (GMP) caused the ileum to contract in a dose-related manner. Tetrodotoxin (3 x 10^{-7} g/ml) and atropine (10^{-6} g/ml) did not inhibit the contractions caused by dibutyryl cyclic GMP (10^{-4} g/ml) in 8 of 10 experiments performed at this concentration. Atropine (10^{-6} g/ml) abolished the contractions caused by nicotine and acetylcholine. Tetrodotoxin (3 x 10^{-7} g/ml) abolished contractions due to nicotine. When the membrane was depolarized, acetylcholine and barium chloride effects were greatly reduced, whereas dibutyryl cyclic GMP (5 x 10^{-5} g/ml) contracted the ileum which it had been unable to do at this concentration in the normal solution. It is suggested that dibutyryl cyclic GMP acted in these experiments by not liberating chemical transmitters, particulary acetylcholine. The action of the drug was stronger in the depolarized muscle due to increased entry of the drug into cells by depolarization of cell membranes. Calcium ions supplied to the contractile elements may be part of the mechanism of this drug effect.

GENERAL

24 SEPARATION OF HUMAN SMALL-INTESTINAL SUCRASE FROM ISOMALTASE. *(E.)* Asp, N. G.; hlqvist, A. (Dept. Nutr., Univ. Lund, Sweden). *BS Lett.* 35(2):303-305, 1973.

A mucosal homogenate was prepared from human proximal jejunum. After ultracentrifugation, the supernatant contained about 10% of the disaccharidase activities. Chromatography on Bio-Gel P-300 gave a major peak, the sucrase-isomaltase complex, containing about 80% of the sucrase and isomaltase activities. The other 20% was eluted in a second peak, displaying considerably lower molecular weight. It was possible to separate the second peak into free sucrase and free isomaltase peaks. Both peaks had maltase activity, and the isomaltase peak also had glucoamylase activity. Free glucose appeared in the range of the isomaltase peak. Thus, solubilization with papain released not only sucrase-isomaltase complex as previously shown, but also some free sucrase and isomaltase from the membrane fragments of human small-intestinal homogenate. It is suggested that the enzyme peak referred to in the literature as sucrase-1 is probably free sucrase.

0225 PROSTAGLANDIN E_1: ITS EFFECTS ON HEPATIC CIRCULATION IN DOGS.

(E.) Geumei, A.; Bashour, F. A.; Swamy, B. V.; Nafrawi, A. G. (Cardiopulmonary Inst. Methodist Hosp., Dallas, Texas). *Pharmacology* 9(6):336-347, 1973.

The effects of i.v., intra-arterial, and intraportal injection of prostaglandin E_1 (PGE_1) on hepatic artery and portal vein flows were studied in anesthetized dogs. I.v. administration of PGE_1 (1 μg/kg) produced an increase in hepatic artery flow, portal vein flow, and portal vein pressure concomitant with a significant decrease in systemic arterial pressure. Injection of the same dose of PGE_1 into the portal vein caused essentially no change in portal vein flow and pressure, or systemic arterial pressure. Intra-arterial injection of PGE_1 increased hepatic artery flow and decreased its resistance, with no change in systemic arterial pressure. The hepatic arterial effect of PGE_1 was dose-dependent and was not abolished after β-adrenoceptor blockade by propranolol (1 mg/kg, i.v.). It is concluded that PGE_1 directly dilates hepatic arteries and indirectly influences the portal venous circulation.

0226 MUCOSAL LESIONS IN THE SMALL INTESTINE OF THE CAT DURING LOW FLOW.

(E.) Ahren, C.; Haglund, U. (Dept. Physiol., Univ. Goteborg, Sweden). *Acta. Physiol. Scand.* 88(4):541-550, 1973.

Examination was made of the mucosal changes produced at the villous tips of the cat small intestine during a mimicked shock situation (regional hypotension at 30 mm Hg during nervous vasoconstrictor fibre activation). Macroscopically, after a 2 hr hypotensive period, petechial bleedings and ulcerations were regularly seen in the mucosa. Microscopic findings showed epithelial lifting of various degrees at the tips of the villi and in some cases a complete denudation of the villous tips. Intraluminal perfusion of a segment with oxygenated saline during the hypotension prevented or greatly reduced the mucosal lesions compared with control segments. However, intraluminal perfusion with nitrogenated saline did not change the mucosal lesions as compared with control. This strongly indicates that hypoxia *per se* is important in the pathogenesis of the mucosal lesions, while the intestinal content (e.g., energy substrates or enzymes) is not. It is suggested that the hypoxia is due to an extravascular shunting of oxygen in the intestinal countercurrent exchanger.

0227 MUCOSAL HEMODYNAMICS IN THE SMALL INTESTINE OF THE CAT DURING REDUCED PERFUSION PRESSURE.

(E.) Lundgren, O.; Svanvik, J. (Dept. Physiol., Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 88(4):551-563, 1973.

An indicator-dilution technique was used to study the effects of reduced arterial inflow pressure and increased venous outflow pressure on mucosal and villous intravascular flows and volumes in the cat small intestine. When reducing arterial inflow pressure from about 100 to about 30 mm Hg, villous plasma volume and mean transit time increased, while villous plasma flow was largely unchanged. Concomitantly, total intestinal blood flow decreased significantly, indicating that a larger fraction of total plasma flow was diverted to the villi at low inflow pressure. Villous hemodynamics was largely unaffected when intestinal blood flow was reduced by increasing venous outflow pressure. Mucosal red cell and plasma flows were affected in the direction of and, often in proportion to, total intestinal blood flow. These results suggest that the autoregulatory capacity of the villous vessels is larger than that of vessels in deeper parts of the mucosa. Therefore, during a reduction in arterial pressure, blood flow is increasingly redistributed from deeper parts of the mucosa to the villous circulation.

0228 RELATIONSHIP OF HQ-275 TO BILIARY EXCRETION AND PORTAL BLOOD FLOW IN DOGS.

(E.) Ochiai, T.; Nagao, T.; Murata, S.; Yoshimoto, K.; Kowa, Y. (Biol. Res. Labs., Tanabe Seiyaku Co., Osaka, Japan). *Jap. J. Pharmacol.* 23(4):575-578, 1973.

A tracheal cannula was inserted in 8 fasted adult mongrel dogs. Tubes were centrally inserted into the common bile duct and through the papilla into the main pancreatic duct. The gallbladder was resected and the accessory pancreatic duct was also ligated and cut. After the biliary and pancreatic juice outflow had reached a steady state, 1-morpholinoacetyl-2-methyl-3-phenyl-4-oxo-1,2,3,4-tetrahydro quinazoline hydrochloride (HQ-275, 3 or 10 mg/kg, i.v.) was administered. Biliary outflow was maximum for the first 30 min. The drug was noted in the biliary excretion in animals where the gallbladder had been resected as well as in rats which had undergone a cholecystostomy. Thus, cholekinetic action did not affect the biliary excretion of the HQ-275. The portion of solid contents/biliary volume excreted after the drug was administered was lower in concentration than cholaneretic agents, indicating that the effect of HQ-275 depends on the hydrocholeretic action which mainly increases the portion of water in biliary excretion. No influence was observed on pancreatic-juice excretion. The drug markedly and dose-dependently increased portal blood flow, a 1 mg/kg dose causing a slight increase in flow and a 30 mg/kg dose resulting in an 86% increase immediately after injection. Femoral artery blood pressure was not changed by a 1 mg/kg dose but fell transiently by 10 mmHg immediately after a 10 mg/kg dose was given. Pulse was slightly increased by HQ-275.

0229 THE ADRENERGIC CONTROL OF LOWER ESOPHAGEAL SPHINCTER FUNCTION. AN EXPERIMENTAL MODEL OF DENERVATION SUPERSENSITIVITY. *(E.)* DiMarino, A. J.; Cohen, S. (Univ. Pennsylvania Hosp., Philadelphia). *J. Clin. Invest.* 52(9):2264-2271, 1973.

To evaluate the adrenergic regulation of lower esophageal sphincter (LES) function, LES pressure, LES relaxation during swallowing, and blood pressure were measured in the anesthetized opossum *Didelphis virginiana* during i.v. administration of alpha and beta adrenergic agonists and antagonists. Studies were done in controls and animals adrenergically denervated with 6-hydroxydopamine. Alpha adrenergic agonists (norepinephrine, phenylephrine) increased LES pressure and blood pressure, while a beta adrenergic agonist (isoproterenol) decreased both pressures. Alpha adrenergic antagonism (phentolamine) reduced basal LES pressure by 38.3%. Beta adrenergic antagonism (propranolol) had no significant effect on either basal LES pressure or percent of LES relaxation with swallowing. After adrenergic denervation with 6-hydroxydopamine, basal LES pressure was reduced by 22.5% but LES relaxation during swallowing was unaltered. In denervated animals, both LES pressure and blood pressure dose-response curves showed characteristics of denervation supersensitivity to alpha but not to beta adrenergic agonists. These studies suggest: that a significant portion of basal LES pressure is dependent on alpha adrenergic stimulation; that LES relaxation during swallowing is not an adrenergically mediated response; and that LES pressure response to alpha adrenergic agonists after 6-hydroxydopamine may serve as a model of denervation supersensitivity in the gastrointestinal tract.

0230 HEMODYNAMIC EFFECTS OF DISTENSION OF THE DOG SMALL INTESTINE. *(E.)* Hanson, K. M. Ohio State Univ. Coll. Med., Columbus). *Am. J. hysiol.* 225(2):456-460. 1973.

tepwise inflation and deflation on lumen pressure nd hemodynamics were studied in 29 isolated auto- erfused segments of dog ileum. An electromagnetic lood flowmeter was used to measure arterial inflow. ntraluminal pressure was measured with a catheter ip pressure transducer. Periods of spontaneous hythmic motor activity were recorded consisting of scillations with an amplitude of about 50 mm Hg. hey had no significant effect on mean vascular esistance and neither impeded nor enhanced mesen- eric blood flow. On ileum distension, the nitial decrease in flow and increase in resistance howed a certain degree of recovery over a period f several min, resulting from attenuation of ini- ial increase in gut lumen pressure. This was at- ributed to stress relaxation of the ileal wall. n active autoregulatory response to the initial decrease in vessel transmural pressure may account for part of the flow recovery. In 13 experiments observations were repeated during intra-arterial infusion of papaverine. There was greater relative decrease in flow and increase in resistance at any given gut lumen pressure in papverinized ileum, probably due to loss of the active autoregulatory component.

0231 MECHANISM OF HYPERALIMENTATION IN THE SUPPRESSION OF UPPER GASTROINTESTINAL SECRETIONS. *(E.)* Towne, J. B.; Hamilton, R. F.; Stephenson, Jr., D. V. (Univ. Nebraska Hosp., Omaha). *Am. J. Surg.* 126(6):714-716, 1973.

The effects of the various components of parenteral hyperalimentation on upper gastrointestinal secretions were studied. Thomas duodenal cannulas were inserted opposite the main pancreatic duct and a Maydl feeding jejunostomy was constructed in each of 5 dogs. The accessory pancreatic duct was ligated and a gastric cannula was placed. The administration of 20% dextrose increased the blood sugar levels from 86 to 720 mg/100 ml. When 20% dextrose plus 5% amino acids were infused, duodenal volume decreased 50.5%, bicarbonate concentration increased 18.7%, bilirubin output decreased 86.2%, amylase output decreased 70.8% and the protein output decreased 73.1%. When 20% dextrose was infused alone, duodenal volume decreased 29.4%, bicarbonate increased 12%, bilirubin output decreased 83.5%, amylase output decreased 39.1% and protein output decreased 86.8%. When 5% amino acids were infused alone, duodenal volume decreased 10.1%, bicarbonate concentration increased 4.6%, bilirubin output decreased 65.4%, amylase output decreased 16.7%, and protein output decreased 63.2%. Suppression of protein secretion after amino acid infusion demonstrated the suppression of proximal small intestinal enzymatic production by the infusion. It is suggested that the elevated blood glucose level stimulated hypothalamic centers, causing reflex suppression of upper gastrointestinal secretions. Similarly, an increase in endogenous insulin secretion resulting from glucose and amino acid infusion could produce this inhibitory effect on proximal small intestinal secretions.

0232 DISAPPEARANCE OF GASTRIN ACROSS THE LUNG. *(E.)* Korman, M. G.; Hansky, J.; Ritchie, B. C.; Watts, J. M.; Maloney, J. E. (Monash Univ., Dept. Med., Melbourne, Australia). *Aust. J. Exp. Biol. Med. Sci.* 51(5):679-687, 1973.

The fate of injected synthetic human gastrin was studied in intact dogs, sheep, and pigs as well as in isolated perfused liver and lungs using radioimmunoassay. The half-life of synthetic human gastrin was similar in all intact animals at approximately 7 min. Acute bilateral nephrectomy and total enterectomy did not alter this half-life. Gastrin did not disappear after passage across the isolated perfused pig liver. However, the disappearance rate for synthetic human gastrin across the isolated perfused lungs of the dog or sheep was identical to that in the intact animal. Studies in the dog undergoing cardiopulmonary bypass indicated that the half-life of synthetic human gastrin was prolonged to 35 min. These studies suggest that the lungs are important in the disappearance of gastrin from the circulation, and that the liver, kidney, and small bowel do not function significantly in this capacity. The high incidence of peptic ulceration in patients with chronic respiratory disease suggests that failure of the lungs to carry out gastrin breakdown may be important in the etiology of this peptic ulceration.

0233 THE EFFECT OF HEMORRHAGE ON HEPATOSPLANCHNIC HEMODYNAMICS, LIVER FUNCTION AND HEPATIC METABOLISM. *(E.)* Krarup, N. (Inst. Physiol., Univ. Aarhus, Denmark). *Acta Physiol. Scand.* 89(2):269-277, 1973.

Following a control period, cats in the postabsorptive state and anesthetized with chloralose were bled 15 ml/kg, approximately 25% of the blood volume. Due to a large decrease in portal flow, the total liver blood flow decreased in parallel to the mean arterial blood pressure, whereas the hepatic arterial flow remained constant. Thus the splanchnic vascular resistance was unchanged, the hepatic arterial resistance decreased, and the gastrointestinal resistance increased after the hemorrhage. The portal venous resistance was also significantly increased. The hemorrhage resulted in hepatic glycogenolysis and peripheral glycolysis, but neither the splanchnic elimination of ethanol, consumption of oxygen, nor hepatic dye elimination was decreased, and the hepatic redox level remained unaltered. The results indicate that, although hemorrhage is accompanied by marked changes in hepatosplanchnic hemodynamics, the intrahepatic distribution of blood flow is not subject to gross alteration. These results do not support transillumination studies in which hemorrhage caused redistribution of the hepatic blood flow, resulting in a decreased number of perfused sinusoids or excessive decrease in the flow through some of the sinusoids. It is suggested that this discrepancy may result from a difference in the degree of bleeding in the two studies.

DIAGNOSTIC PROCEDURES

0247 FECAL CHYMOTRYPSIN: A RELIABLE INDEX OF EXOCRINE PANCREATIC FUNCTION IN CHILDREN.
(E.) Bonin, A.; Roy, C. C.; Lasalle, R.; Weber, A.;
Morin, C. L. (Saint Justine Hosp., Montreal, Canada).
J. Pediatr. 83(4):594-600, 1973.

The 72-hr fecal output of chymotrypsin, expressed
as mg/kg, was measured in 64 children with pancrea-
tic disease (60 with cystic fibrosis, 3 with chronic
relapsing pancreatitis, and 1 with exocrine pancrea-
tic insufficiency and bone marrow dysfunction)
and in 57 children with various hepatic and intesti-
nal disorders. Fecal chymotrypsin output clearly
listinguished 57 cystic fibrosis patients with
steatorrhea from both the 35 control subjects and
7 children with cystic fibrosis without fat malab-
sorption. Three of the children with pancreatic
lisease other than cystic fibrosis did not have
si~nificant pancreatic insufficiency, but the fecal
hymotrypsin in this group differed significantly
from that of the controls. Values in hepatic dis-
rders, gluten-induced enteropathy, chronic diarrhea
rithout fat malabsorption, intractable diarrhea,
nd the short bowel syndrome did not differ from
ontrol values. The only value (1.3 mg) within
he range observed in pancreatic disorders was seen
n a case of intestinal scleroderma. Duodenal en-
yme concentrations in 35 children correlated well
ith fecal measurements in 5 cases of primary pan-
reatic disease with significant achylia.

248 DIAGNOSIS OF PANCREATIC EXOCRINE INSUFFICIENCY BY FECAL CHYMOTRYPSIN ACTIVITY.
.) Moeller, D. D.; Dunn, G. D.; Klotz, A. P.
Jniv. Kansas Med. Ctr., Kansas City, Mo.). *Am. J.*
g. Dis. 18(9):792-796, 1973.

ntrol subjects (13 males and 1 female aged 24-70
) and 9 male patients (aged 30-64 yr) with severe
ncreatic exocrine insufficiency were carefully
udied to establish normal values of fecal chymo-
ypsin activity. Diagnoses in the 9 patients in-
uded status after Whipple operation for carcinoma
ampulla of Vater (1), chronic calcific pancreati-
s (4), chronic pancreatitis; status after Billroth
(1), status after Whipple operation for carcinoma
head of the pancreas (1), calcific pancreatitis
), and chronic pancreatitis with cirrhosis (1).
agnoses in the control subjects included irritable
lon (8), chronic duodenal ulcer and Parkinson's
sease (1), chronic alcoholism (1), chronic diarrhea
th osteomalacia (1), acute gastritis (1),
pendicitis (1), and hiatal hernia (1). Mean
lues for fecal chymotrypsin were uniformly
normal in patients with pancreatic exocrine insuffi-
ency. This study supports previous work in
lidating this test as a simple but effective
thod of screening patients with steatorrhea for
diagnosis of pancreatic exocrine insufficiency.

9 DIAGNOSTIC YIELD OF FIBRE-OPTIC ENDOSCOPY IN THE OPERATED STOMACH. *(E.)* Cotton, P.
Rosenberg, M. T.; Axon, A. T. R.; Davis, M.;
rce, J. W.; Price, A. B.; Stevenson, G. W.;
dram, R. (St. Thomas Hosp., London, England).
J. Surg. 60(8):629-632, 1973.

Fiber-optic instruments were used on 212 occasions to examine 177 patients who were symptomatic after peptic ulcer surgery. The time lapsing from the original operation to endoscopy ranged from 2-42 yr after partial gastrectomy, 2 months to 12 yr after vagotomy and pyloroplasty, and 1-23 yr after gastroenterostomy. Diagnoses other than gastritis were reached in 83 patients and included 46 patients with ulcers. Five ulcers were not seen; in 4 cases this resulted from inadequate equipment early in the series. Radiology detected only 60% of the ulcers and raised many false-positive diagnoses. Many originally mistaken interpretations were corrected by expert review of the radiographs. Retained suture materials seen by endoscopy were removed using biopsy forceps. Gastric mucosal congestion and gastritis were common in the operated stomach, but the clinical significance of these changes remains obscure in the absence of a control series. Fiber-optic endoscopy is now an essential part of the investigation of patients who are symptomatic following ulcer surgery.

0250 AUSTRALIA ANTIGEN IN LIVER TISSUE. AN IMMUNOFLUORESCENT AND IMMUNOELECTRON MICROSCOPIC STUDY. *(E.)* Shikata, T. (Fac. Med., Univ. Tokyo, Japan). *Jap. J. Exp. Med.* 43(4):231-245, 1973.

An immunofluorescent as well as immunoelectron microscopic study of human liver tissue was made during the course of various liver diseases: fulminant hepatitis (4 cases), subacute hepatitis (1), chronic hepatitis (30), cirrhosis (2), and malignant hepatoma (8), in order to clarify the localization of Australia antigen (Au-antigen) in the tissue and cells. Au-antigen stained specifically by immunofluorescence was found only in the cytoplasm of hepatocytes and, to a lesser extent, in the mesenchymal cells; no obvious Au-antigen was identified in the hepatocyte nucleus. The distribution of hepatocytes containing fluorescent Au-antigen in liver tissue was very irregular, and showed 2 patterns. In one pattern almost all parenchymal cells in some areas, in the sublobular level, contained Au-antigen. In the other pattern, solitary parenchymal cells with Au-antigen were scattered sporadically in the liver cell plates. It is suggested that the former is an early stage of Au-antigen proliferation in some parts of liver tissue and the latter is a late stage. In the latter, scattered cells containing fluorescent Au-antigen were rounded and resembled acidophilic bodies. These degenerative hepatocytes contained many particles measuring about 200 Å in diameter. These particles and tubular structures were also present in the lysosomes of hepatocytes. No nuclear localization was established. In fulminant hepatitis, stainable Au-antigen was very scanty, even in a case with Au-antigenemia. On the other hand, immunoglobulin and complement were detected in the necrotic areas by immunofluorescence method, suggesting an immuno complex was involved in liver cell damage. In malignant hepatoma, stainable Au-antigen was not usually found in hepatoma cells, but it was present in noncancerous hepatocytes. The immunofluorescent method revealed that Au-antigen persisted for 4 weeks in organ cultures of human fetal liver which were inoculated with serum from an Au-antigen-positive patient with acute hepatitis.

0251 ANGIOGRAPHIC DIFFERENTIATION BETWEEN INFLAMMATORY DISEASE AND CARCINOMA OF THE PANCREAS. *(E.)* Tylen, U. (Univ. Hosp., Lund, Sweden). *Acta Radiol.* 14(3):257-272, 1973.

Differential diagnosis between pancreatitis and carcinoma of the pancreas were investigated angiographically in 19 patients (13 males and 6 females) in whom an incorrect diagnosis had been made. The diagnosis of carcinoma was particularly difficult in the presence of expansive lesions and calcifications; an incorrect positive diagnosis was often made when vascular changes were strictly localized. It is suggested that coning-down of the roentgen beam, compression, superselective catheterization, and pharmacological agents are possible means of improving the quality of the examination. Repeat angiography at short intervals is recommended in doubtful cases so that malignant changes can be detected while radical surgery is still possible. Technical quality and experience in pancreatic angiography are both extremely important since only the demonstration of tumor vessels, though scanty in this type of growth, permits a definite diagnosis of carcinoma of the pancreas.

0252 ACCURACY OF ANGIOGRAPHY IN THE DIAGNOSIS OF CARCINOMA OF THE PANCREAS. *(E.)* Tylen, U. (Univ. Hosp., Lund, Sweden). *Acta Radiol. Diag.* 14(1):449-466, 1973.

Angiographic findings in 116 patients with verified carcinoma of the pancreas were examined in retrospect. The growth involved the head of the pancreas in 87 cases, the body in 21, and the tail in 8. A correct preoperative diagnosis had been made in 79 and a retrospective diagnosis was possible in an additional 30 patients. An incorrect positive diagnosis was made in 18 patients preoperatively and in 5 patients retrospectively, a common cause being localized pancreatitis. Of the 18 incorrectly diagnosed cases, 5 had inflammatory pancreatic changes, another had biliary tract disease, and 1 had stenosis of the papilla of Vater. Variations in the vascular anatomy and a poor technique contributed to diagnostic errors. Although large carcinomas can be easily diagnosed by angiography, difficulties may arise when vascular changes are small and localized. Irregularities in the blood vessels are usually more pronounced when they are encased by pancreatic carcinoma than in pancreatitis.

0253 SELECTIVE ARTERIOGRAPHY IN THE DIAGNOSIS OF CHRONIC INFLAMMATORY PANCREATIC DISEASE. *(E.)* Khademi, M.; Lazaro, E. J.; Rickert, R. R. (Coll. Med. Dent. New Jersey, Newark). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 119(1):141-150, 1973.

Selective superior mesenteric and celiac angiography was performed on 78 patients suspected of having chronic pancreatitis. Positive angiographic findings were confirmed by surgical inspection, pathological examination, or clinical, laboratory, and conventional roentgenological studies in 59 of these 78 cases (75%). Angiography gave false-positive results in 10 cases, false-negative results in 2 cases, and equivocal results in 8 cases. Focal or generalized pancreatic blush, small arterial beading and irregularity were the most common findings. Hypervascularity and enlargement of the organ in acute recurrent or active stages and hypovascularity in advanced fibrosis were observed. Nonfunctioning splenic vein, seen in 14% of cases is the most reliable sign of chronic pancreatitis in absence of adjacent arterial encasement.

0254 PERITONEOSCOPY: ITS VALUE IN THE DIAGNOSIS OF LIVER DISEASE. *(E.)* Czaja, A. J.; Steinberg, A. S.; Saldana, M.; Marin, G. A. (Philadelphia Gen. Hosp., Pa.). *Gastrointest. Endosc.* 20(1):23-25, 1973.

Liver specimens from 36 consecutive cadavers were obtained using closed needle biopsy and guided biopsy performed under peritoneoscopy (34 of the 36 cases). Visual inspection of the liver at peritoneoscopy was diagnostic by itself in 16 cases (44.5%). Micronodular cirrhosis, metastatic tumor, and severe passive congestion were diagnosed by visualization alone. Tissue obtained by guided needle biopsy was diagnostic in 31 of the 36 cadavers (86.2%). Of the 34 specimens obtained by the guided technique, 31 were diagnostic (91.2%). Combining visual findings with the histology of the specimens obtained by guided biopsy gave a correct diagnosis in 97% of the 34 cases in which peritoneoscopy was performed. A correct diagnosis by blind needle biopsy specimens was made in 32 of the 36 cadavers. Cirrhosis, fatty liver, congestion, and inflammation were readily diagnosed by closed biopsy, but 4 of the 5 cases of metastatic liver disease were missed by this procedure.

0255 PROSPECTIVE UPPER GASTROINTESTINAL SERIES IN THE EVALUATION OF BURNED CHILDREN. *(E.)* Law, E. J.; MacMillan, B. G.; Gelfand, D. W.; Day, S. B. (Shriners Burns Inst., Cincinnati, Ohio). *Am. J. Surg.* 126(3):366-371, 1973.

Upper gastrointestinal series were used to detect possible ulcers in children up to 15 yr old. In 152 patients 214 studies were performed. Ulcers were demonstrated unequivocally in the stomach or duodenum in 3.4% of the patients, while suspected ulcers were present in another 8 cases, for a combined incidence of 7.4%. Most of these patients were asymptomatic. Superior mesenteric artery syndrome in some degree was revealed in 12 patients (5.9% of all cases). A significant number of burned patients therefore had radiographically detectable disease, and this awareness aided in clinical management. No complications resulted from the performance of these studies.

0256 THE FOLIC ACID URINARY EXCRETION TEST IN THE DIAGNOSIS OF INTESTINAL MALABSORPTION OF FOLIC ACID. *(E.)* Elsborg, L. (Dept. Med.

II., Arhus Univ., Denmark). *Danish Med. Bull.* 20(3):102-104, 1973.

Intestinal absorption of folic acid has been determined by assay of urinary excretion after an oral dose of ^{3}H-folic acid. To determine absorption i.m., an oral dose of 200 μg ^{3}H-folic acid combined with 15 mg non-labeled folic acid i.m. is suitable. This yielded urinary excretion of 30-54% in normal subjects. This test was also performed on 54 patients with malabsorption and normal folate status and on 18 patients with deranged folate status caused by postgastrectomy syndrome (5), celiac disease (3), idiopathic steatorrhea (3), and extensive resections of small intestines (2). The folic acid urinary excretion test did not show a significant difference for patients with malabsorption and a normal folate status, but decreased urinary excretion was found in patients with folate deficiency from intestinal malabsorption. These observations indicate a strong correlation between the degree of folic acid malabsorption and the urinary excretion test.

0257 RADIOLOGICAL AND ENDOSCOPIC STUDY OF THE ESOPHAGUS IN SCLERODERMA. *(Fr.)* Petite, J. P.; Soussaline, M.; Jodelet, P.; Chaput, J. C.; Guerre, J.; Housset, E. (Broussais Hosp., Paris, France). *Arch. Fr. Mal. App. Dig.* 62(2):105-112, 1973.

Clinical, radiological, and esophagoscopic examinations were performed on 33 patients (27 women and 6 men, aged 33-70 yr) with generalized scleroderma. Of these patients, 11 had dysphagia, 7 had manifestations of gastroesophageal reflux, and 5 had dysphagia associated with a reflux syndrome. No clinical symptoms of esophageal involvement were found in 20 patients. Radiological examinations demonstrated that 26 of these 33 patients had disturbances in esophageal motor activity. The most common endoscopic manifestations, found in these same 26 patients, were absence of peristaltic contractions in the lower part of the esophagus and the persistence of "water lakes" for at least 30 sec after administration of a few ml of water while the patient was lying down. Esophageal reflux was diagnosed in 17 patients, hiatus hernia in 6, peptic esophagitis in 10, and peptic stenosis in 4. It is recommended that all patients with generalized scleroderma undergo radiological and esophagoscopic examinations since many have no clinical symptoms of esophageal involvement.

0258 DETECTION OF IMMUNOGLOBULINS IN PARAFFIN-EMBEDDED LIVER BIOPSIES. STUDIES IN 100 ATIENTS WITH SPECIAL REGARD TO IMMUNOLOGICAL FIND-NGS IN ACTIVE CHRONIC HEPATITIS. *(E.)* Husby, G.; lomhoff, J. P.; Skrede, S.; Elgio, K.; Gjone, E. Rikshosp. Univ. Hosp., Oslo, Norway). *Scand. J. astroenterol.* 8(7):621-629, 1973.

araffin-embedded liver biopsies were examined by irect immunofluorescence for immunoglobulins and myloid in patients with established or suspected iver disease. In all 12 active chronic hepatitis atients serum IgG was increased, and smooth muscle antibodies were present. Of these 12, 4 had Australia antigen in serum. Immunoglobulins were present in the liver, mainly within mononuclear cells resembling plasma cells. More than 80% of the immunolobulins were IgG, about 15% were IgA, and less than 5% were IgM. In primary biliary cirrhosis, most of the 9 patients had increased serum IgM, and 80% had mitochondrial antibodies. In the liver, the immunological activity was low, but IgM-containcells were more frequent than in other types of liver disease. Also in alcoholic cirrhosis (9 patients) and cryptogenic cirrhosis (4 patients), the immunofluorescence was much less pronounced than in active chronic hepatitis. In the 6 acute hepatitis cases, there was a remarkably high amount of IgA in the liver tissue. A shift from IgA to IgG was seen when acute hepatitis progressed into chronic disease (8 cases). In 15 cases with normal histology, no immunoglobulin was detected in the liver tissue. In 7 patients with clinical and histological evidence of amyloidosis of the liver, varying amounts of fluorescent amyloid material were present. These results indicate that immunofluorescence studies may be valuable for classifying liver diseases. It is also indicated that humoral immunological mechanisms are in some way involved.

0259 INFLUENCE OF AGE, SEX AND DISEASE ON THE DIAMETER OF THE COMMON BILE DUCT. *(Dut.)* Holtzer, J. D.; Endeman, H. J. (Univ. Hosp., Utrecht, Netherlands). *Tijdschr. Gastroenterol.* 15(5):403-405, 1972.

GASTROINTESTINAL DISEASES

ESOPHAGUS

0325 DISAPPEARANCE OF MULTIPLE ESOPHAGEAL DIVERTICULA FOLLOWING TREATMENT OF ESOPHAGITIS: SERIAL ENDOSCOPIC, MANOMETRIC, AND RADIOLOGIC OBSERVATIONS. *(E.)* Bender, M. D.; Haddad, J. K. (VA Hosp., San Francisco, Calif.). *Gastrointest. Endosc.* 20(1):19-22, 1973.

Multiple esophageal diverticula were demonstrated endoscopically, but not radiologically, in a 56-yr-old white male in association with hiatus hernia, acid reflux, and esophagitis. The diverticula disappeared during the course of intensive medical therapy of esophagitis. Serial manometric studies, combined with acid perfusion, helped elucidate a possible pathogenetic mechanism. This case suggests that a reversible, treatable, "pre-diverticular" stage occurs in the natural history of esophageal diverticula. It is suggested that patients with radiographic or endoscopic diverticula be evaluated with serial endoscopic, roentgenologic, and manometric studies.

0326 A CLINICO-PATHOLOGICAL STUDY OF SOME FACTORS INFLUENCING SURVIVAL IN CANCER OF THE OESOPHAGUS: A SURVEY OF TEN YEARS' EXPERIENCE. *(E.)* Nicks, R.; Green, D.; McClatchie, G. (Roy. Prince Alfred Hosp., Sydney, Australia). *Aust. J. Surg.* 43(1):3-13, 1973.

Records of 332 patients with esophageal carcinomas seen over a 10-yr period were reviewed. Of the 332 carcinomas, 37 were situated in the upper cervical and hypopharyngeal regions; 295 were thoracic in which cases the lower third and cardia were more frequently affected (156 cases as compared with 91 in the middle third and 30 in the upper). The most frequent symptoms were increasing dysphagia with loss of appetite. Many patients also experienced pain localized in the cervical region; a smaller number experienced vomiting, hoarseness, and cough. In 314 cases where the histological type was identified, the tumor was a squamous cell carcinoma in 213 cases, an adenocarcinoma in 78, and of undifferentiated type in 23 cases. The carcinoma had advanced through the wall of the esophagus, had involved the lymphatic glands, or had metastasized in 305 of the 332 patients. A severe grade of anaplasia was noted in 156, moderate in 67, and minimal in 55. The 5-yr survival rate was 4%. Survival in terms of the site of carcinoma suggests that those located in the upper thoracic and lower cervical regions are fatal. The only 3-yr survivors were those patients undergoing resection or radical radiotherapy, 15% and 8% survivors, resp. The lack of any 2-yr survivors among patients where excision was incomplete emphasizes the need for extensive en-bloc local excision well beyond the carcinoma, throughout its length, and including periesophageal tissues, pleura, and all draining lymph nodes.

0327 ADENOCARCINOMA IN THE COLUMNAR EPTHELIAL LINED LOWER (BARRETT) OESOPHAGUS. *(E.)* Hawe, A.; Payne, W. S.; Weiland, L. H.; Fontana, R. S. (Mayo Clin., Rochester, Minn.). *Thorax* 28(4): 511-514, 1973.

Patients (4 males and 1 female, aged 39-75 yr) with Barrett esophagus developed adenocarcinoma of the esophagus at sites cephalad from the anatomic cardia but separated from it by a definite segment of columnar lined esophagus. Similar cases (12) have been reported in the literature. Of 85 patients in whom a clinical diagnosis of benign Barrett esophagus was made in the 20-yr period 1950-69, 2 subsequently developed esophageal cancer. Since its description in 1950 by Barrett, the columnar epithelial-lined lower esophagus has been encountered with increasing frequency. The full clinical implications of this unusual condition are only partially appreciated at this time, and the present results support earlier suggestions that the condition may be premalignant.

0328 EXPERIMENTAL AND CLINICAL STUDIES ON THE ACTION MECHANISM OF FUNDOPLICATION. *(Ger.)* Siewert, R.; Jennewein, H. M.; Waldeck, F.; Peiper, H. J. (Clin. Gen. Surg., Univ. Gottingen, Germany). *Langenbecks Arch. Chir.* 333(1):5-22, 1973.

Pressure studies were performed on dogs and patients who had undergone fundoplication to determine what happens to the lower esophageal sphincter and whether the fundal cuff can act as a sphincter. In the dog, myotomy alone had little effect on resting pressure at the sphincter but did cause gastroesophageal reflux. More pronounced changes were noted in sphincter pressure after injection of pentagastrin, carbachol and, to a lesser extent, glucagon. Total circular myomectomy reduced sphincter pressure to 3.6 mm Hg and caused reflux; peptide hormones no longer had an effect on sphincter pressure. Fundoplication in dogs with intact lower esophageal sphincters resulted in a high-pressure zone which acted as a normal sphincter in its responses to polypeptide hormones. Similar results were obtained by fundoplication following myotomy. Combination of fundoplication with total myomectomy gave a resting pressure of 13.6 mm Hg in the fundal cuff which was more than doubled (33.3 ± 10.8 mm Hg) by pentagastrin but was reduced only slightly by glucagon. No reflux was detected in dogs which had undergone any of these fundoplication procedures. Thus, in fundoplication the fundal cuff forms a high-pressure zone which reacts to gastrointestinal hormones in the same way as the lower esophageal sphincter and prevents gastrointestinal reflux. These findings were confirmed on 15 patients who had undergone fundoplication. *In vitro* experiments on isolated muscle strips from the dog showed that anterior wall of the fundus, right under the cardia, reacted to pentagastrin in the same way as strips from the lower esophageal sphincter. In contrast, strips of fundal mucosa near the larger curvature reacted only slightly to large doses of pentagastrin. Thus, it is important that the fundal cuff be formed from the anterior fundus close to the cardia since only muscles from this area can react in a way similar to those of the lower esophageal sphincter.

STOMACH

0348 SUPERFICIAL GASTRIC EROSIONS. RESPONSE TO SURGICAL TREATMENT. *(E.)* Wilson, W. S.; Gadacz, T.; Olcott, III, C.; Blaisdell, F. W. (San Francisco Gen. Hosp., Calif.). *Am. J. Surg.* 126(2):133-140, 1973.

A study was made of 56 patients who underwent surgery for hemorrhage from superficial gastric erosions. In 28 patients trauma, sepsis, and recent surgery were predisposing factors. A second group of 28 patients consisted of those with alcoholism, excessive aspirin intake, low cardiac output, diabetes, and idiopathic factors. These 2 groups did not differ significantly in age nor in postoperative rebleeding rates. Of 21 patients undergoing vagotomy and drainage with systematic suture ligation of visible erosions, whether or not they were bleeding at gastrotomy, rebleeding occured in 2 (9.5%). Of 19 patients who had vagotomy and drainage without suture ligation, rebleeding occurred in 9 (47%). This difference is statistically significant. Of 9 patients with partial gastrectomy without vagotomy, 4 (44%) had rebleeding; 1 total gastrectomy resulted in death from sepsis. Rebleeding rates correlated well with the amount of blood transfused preoperatively. Mortality correlated better with the severity of the patient's illness prior to bleeding than with the operation performed. A study of gastric physiology and mucosal microvascular anatomy, suggests that bleeding results from previous or recurrent episodes of mucosal ischemia and that vagotomy lessens the tendency to further erosion by decreasing the acid output in these stressed patients. Suture ligation is useful in preventing further venous hemorrhage from erosions already present.

0349 PSEUDOLYMPHOMA OF THE STOMACH. *(E.)* Wright, C. J. E. (Dept. Pathol., Univ. Coll., Cork, Ireland). *Hum. Pathol.* 4(3):305-318, 1973.

Pseudolymphoma of the stomach was diagnosed in 5 patients (4 males and 1 female aged 36-62 yr). The duration of the symptoms ranged from 1-10 yr. Malignancy was apparent in 3 cases, based on clinical and operative impressions, and was questionable in the remaining 2. Partial gastrectomy was performed in 4 cases, total gastrectomy in 2 (1 of the former patients returned 14 months later for the total operation). Survival ranged from 6 weeks to 22 yr with this latter patient still living. These cases shared several points in common such as long clinical history, site of involvement, notably flat lesions, presence of ulceration and fibrosis, and distinctive lymphoreticular proliferation. These features suggest an entity distinct from malignant lymphoma. It is suggested that the lack of nonneoplastic lesions closely simulating reticulum cell sarcoma should be enough to avoid confusing that disease with pseudolymphoma of the stomach.

0350 ANTRO-PYLORIC GASTRINOMA ASSOCIATED WITH PANCREATIC NESIDIOBLASTOSIS AND PROLIFERATION OF ISLETS. *(E.)* Larsson, L. I.; Ljungberg, O.; Sundler, F.; Hakanson, R.; Svensson, S. O.; Rehfeld, J.; Stadil, F.; Holst, J. (Dept. Histol., Univ. Lund, Sweden). *Virchows Arch. (Pathol. Anat.)* 360(4):305-314, 1973.

An adenoma in the antropyloric mucosa of a 66-yr-old male patient with recurrent duodenal ulcers was identified by immunofluorescence as a gastrinoma. Resected pancreatic tissue showed greatly increased numbers of islets and ducts. Insulin and glucagon cells were revealed by immunofluorescence not only in the islets but also in the duct epithelium. Signs suggesting neoformation of islets from the duct epithelium were observed. The combination of gastrinoma and pancreatic nesidioblastosis with proliferation of islets may be part of a more generalized endocrine disorder. Alternatively, the islet proliferation may be secondary to trophic influence from the gastrinoma.

0351 GASTRIC EMPTYING IN PATIENTS WITH ACHLORHYDRIA OR HYPOSECRETION OF HYDROCHLORIC ACID. *(E.)* Halvorsen, L.; Dotevall, G.; Walan, A. (Sahlgren's Hosp., Goteborg, Sweden). *Scand. J. Gastroenterol.* 8(5):395-399, 1973.

Gastric emptying was investigated in 21 patients (8 males and 13 females, aged 33-76 yr) with achlorhydria (15 cases) or hyposecretion (6 cases) compared to control subjects (10 males and 9 females, aged 22-63 yr), using the modification of Hunt's method described by George. Half-time as well as emptying time was significantly more rapid in patients with achlorhydria or hyposecretion, 8.7 min and 52.3 min, resp., as compared with 13.4 min and 74.9 min, resp., for control subjects. No correlation was noted between half-time or emptying time and age. No significant sex differences were found among patients or controls. These findings are in contrast with reports using $^{51}CrCl_3$ as non-absorbable gastric indicator. It is suggested that chromic chloride losses by adsorption onto mucus at high pH are considerably greater than those of the phenol red used in the present study. This may partly explain the varying results obtained.

0352 IMMUNE REACTIONS IN DRUG-INDUCED GASTRITIS. *(Fr.)* Cornet, A.; Carnot, F.; Hartmann, L.; Barbier, J. P. (Laennec Hosp., Paris, France). *Sem. Hop. Paris* 49(23):1649-1656, 1973.

In 12 patients with gastritis and 6 controls with dyspepsia, immunofluorescent staining was used to detect cells producing IgA, IgG, and IgM in the fundal mucosa. Of these patients, 6 (3 men and 3 women, aged 23-54 yr) had drug-induced gastritis caused by ingestion of aspirin in 4 cases, aspirin and indomethacine in 1, and aspirin and diazepam in 1; the remaining 6 patients had chronic forms of gastritis. While biopsies from controls contained only 1 or 2 cells producing immunoglobulins in 5 or 6 microscope fields, biopsies from 10 of the 12 patients with gastritis contained large numbers of immunocompetent cells, particularly those producing IgA. Of the remaining 2 patients who had no evidence of immunocompetent cells in the gastric fundus, 1 had agammaglobulinemia and the other was examined 6 days after a suicide attempt in which he ingested aspirin and diazepam; gastroscopic findings were normal at this time. Serum immunoglobulin levels remained almost unchanged in patients with gastritis although serum glycoprotein levels were increased in some cases. In severe drug-induced gastritis lasting change sometimes occurred in glandular tissue. Acute gastritis regressed, but the immunological reaction persisted for a much longer time.

STOMACH

Peptic Ulcers

0372 STIMULATION OF MURINE GASTRIC HISTIDINE DECARBOXYLASE ACTIVITY BY SHEEP RED BLOOD CELL (SRBC) IMMUNIZATION. *(E.)* Moore, T. C.; Sinclair, M. C.; Lemmi, C. A. E. (Harbor Gen. Hosp., Torrance, Calif.). *Surgery* 74(3):444-446, 1973.

The effect of sheep red blood cell immunization on total stomach histidine decarboxylase activity was studied in 42 inbred Lewis rats from 1-9 days after immunization. ^{14}C-Histidine and pyridoxal phosphate were incubated with stomach tissue for 3 hr, and the ^{14}C-histamine produced was converted to benzenesulfonyl histamine (BSH) which was then purified by repeated recrystallization. The mean increase in histidine decarboxylase activity was from 77,061 to 516,572 cpm/100 mg BSH/g stomach. Prior studies had shown an increase in the urinary excretion of histamine and an increase in splenic histidine decarboxylase activity following sheep red blood cell immunization of Lewis rats. An immune response-related increase in the production and release of histamine by the stomach through an increase in histidine decarboxylase activity may be involved in the increased incidence and lethality of gastroduodenal ulceration and bleeding which occur in severe immune challenge situations such as bacterial sepsis and organ transplantation.

0373 EFFECT OF TRUNCAL, SELECTIVE AND HIGHLY SELECTIVE VAGOTOMY ON GASTRIC EMPTYING AND INTESTINAL TRANSIT OF A FOOD-BARIUM MEAL IN MAN. *(E.)* Wilkinson, A. R.; Johnston, D. (Gen. Infirm., Leeds, England). *Ann. Surg.* 178(2):190-193, 1973.

Gastric emptying of a food-barium meal was measured radiographically in 13 patients with duodenal ulcer without pyloric stenosis before operation, and in well-matched groups of patients who were in good health more than 1 yr after highly selective vagotomy (14), truncal vagotomy and pyloroplasty (12) and bilateral selective vagotomy and pyloroplasty (10). All but 2 patients were men. In each patient, the vagotomy was complete on insulin testing in the early postoperative period. The meal began to leave the stomach slightly, but not significantly earlier in patients after truncal and selective vagotomy with pyloroplasty than it did in preoperative patients or patients after highly selective vagotomy. Gastrointestinal transit was significantly increased in patients after truncal or selective vagotomy with pyloroplasty and was more rapid than in duodenal ulcer patients before operation. In patients with highly selective vagotomy, small-bowel transit was slightly faster than in duodenal ulcer patients, but was much less rapid than in patients after truncal or selective vagotomy with pyloroplasty. It is suggested that gastric emptying and small-bowel transit times are closer to normal in patients who have undergone highly selective vagotomy than in patients who have undergone truncal or selective vagotomy with pyloroplasty. There was no evidence of delayed gastric emptying after highly selective vagotomy.

0374 STIMULATION OF GASTRIC SECRETION AND GASTRIN RELEASE BY SINGLE ORAL DOSES OF CALCIUM CARBONATE IN MAN. *(E.)* Levant, J. A.; Walsh, J. H.; Isenberg, J. I. (VA Hosp., Los Angeles, Calif.). *N. Engl. J. Med.* 289(11):555-558, 1973.

In 13 fasting men (mean age 48 yr) calcium carbonate (2 g, p.o.) produced a significant increase in gastric acid secretion above basel levels for 2 hr. Of these 13 patients, 7 had active duodenal ulcers, 5 had no gastrointestinal disease, and 1 had reflux esophagitis. Serum gastrin concentration increased significantly 30 and 60 min after administration of calcium carbonate. No significant change in acid secretion or serum gastrin occurred after administration of sodium bicarbonate (2 g, p.o.). In additional tests, a significant increase in acid secretion occurred in each of 5 subjects given calcium carbonate (0.5 g, p.o.). Single oral doses of calcium carbonate thus stimulate gastric acid secretion and gastrin release in fasting subjects with and without duodenal ulcer.

0375 INFLUENCE OF LACTOSE INTOLERANCE ON THE BONES OF PATIENTS AFTER GASTRECTOMY. *(E.)* Kocian, J.; Vulterinova, M.; Bejblova, O.; Skala, I. (Postgrad. Med. Inst., Prague, Czechoslovakia). *Digestion* 8(4):324-335, 1973.

The index bone area (corticodiaphyseal index) was measured in 167 patients (91 men and 76 women, aged 31-79 yr) after partial gastrectomies (Billroth I and Billroth II) for peptic ulcer; the average time which had elapsed after surgery was about 9 yr. Values were compared with those found in 395 clinically normal subjects, aged 16-96 yr, with no history of milk intolerance. Significantly lower index bone areas were found in gastrectomized patients with lactose intolerance than in the controls. These values were significantly higher in patients without lactose intolerance than in those with lactose intolerance. The findings indicate that the width of the cortical layer in the clavicle decreases more rapidly with age in gastrectomized patients with lactose intolerance than in patients without lactose intolerance. It is concluded that lactose intolerance plays an important role in the etiology of disorders of calcium metabolism and in the development of bone degeneration.

0376 HIGH GASTRIC ACID SECRETION AFTER VAGOTOMY AND PYLOROPLASTY IN MAN - EVIDENCE FOR NONVAGAL MEDIATION. *(E.)* Moore, J. G. (Univ. Utah Coll. Med., Salt Lake City). *Am. J. Dig. Dis.* 18(8):661-669, 1973.

Twenty-four-hr basal acid collections and 4-hr insulin-stimulated gastric secretory tests were obtained in 21 male patients (aged 24-63 yr) who had vagotomy and pyloroplasty for duodenal ulcer disease from 2 to 11 yr earlier. Of these 21 patients, 11 demonstrated high basal acid secretory rates; all of these had "inadequate vagotomies" by most criteria which are based on the assumption that high secretory values represent vagal-mediated gastric secretion. However, all 9 completely studied patients in this group had maximal basal hourly secretory rates exceeding maximal insulin-stimulated hourly rates. It is argued that this observation is not compatible with the interpretation of vagal-mediated basal secretion because with an intact vagus the maximal insulin-stimulated hourly rate should exceed the maximal basal hourly rate. Regardless of the amount of basal acid secretion in the postvagotomy and pyloroplasty stomach, it is suggested that the secretion is largely nonvagal mediated, and surgery for ulcer recurrence in such patients should not center on revagotomy.

0377 EFFECTS OF ANTRECTOMY ON THE GASTRIC MUCOSA OF THE RAT. *(E.)* Capoferro, R.; Nygaard, K. (Univ. Inst. Pathol., Oslo, Norway). *Scand. J. Gastroenterol.* 31(3):347-352, 1973.

The size of the gastric mucosa and the parietal cell population were estimated in adult, male rats 100 days after antrectomy and Roux-en-Y gastrojejunostomy. Glandular mucosal volume was reduced from 411 to 229 mm^3 following complete antrectomy, to 351 mm^3 following incomplete antrectomy, and to 310 mm^3 after pentagastrin was introduced to antrectomized rats. The parietal cell density was reduced from 101 to 76 x 10^3/mm^3 when the antrectomy was complete and to 90 x 10^3/mm^3 with incomplete antrectomy. When pentagastrin (200 μg/kg) was chronically administered to antrectomized rats, the parietal cell density was increased to 153 x 10^3/mm^3. It is suggested that the withdrawal of antral gastrin is an important factor in the pathogenesis of the gastric atrophy which occurs after partial gastrectomy. No significant gastritis was found.

SMALL INTESTINE

0403 INTESTINAL BYPASS OPERATIONS FOR OBESITY. *(E.)* Baber, Jr., J. C.; Hayden, W. F.; Thompson, B. W. (Univ. Arkansas Med. Ctr., Little Rock). *Am. J. Surg.* 126(6):769-772, 1973.

Ninety jeunoileal bypasses were performed on 86 patients (66 women and 20 men, aged 17-46 yr) to control morbid obesity. The 15 and 10 inch anastomosis was well tolerated, but only 2 of 10 patients are within the normal weight range after 4-10 year. The 14 and 4 inch bypass produced an average weight loss of 100 pounds in 58 patients but resulted in 2 deaths due to progressive liver disease and in 26 of the 29 nonfatal complications in this series. These nonfatal complications included electrolyte imbalance (8), acute cholecystitis (6), incisional hernia (3), wound infection (2), renal calculi (3), evisceration (1), intestinal obstruction (1), intussusception (1), and stress ulcer (1). The 15 and 5 inch jejunoileal end to side anastomosis appears to give better results. Although the follow-up period has been only 3-4 months, complications have been few and the 18 patients have lost 28-86 pounds.

0404 CONCOMITANT OCCURRENCE OF NEUROFIBROMATOSIS AND CARCINOID OF THE INTESTINE. *(E.)* Arnesio, B.; Idvall, I.; Ihse, I.; Telenius, M.; Tylen, U. (Univ. Hosp., Lund, Sweden). *Scand. J. Gastroenterol.* 8(7):637-643, 1973.

Von Recklinghausen's neurofibromatosis with multiple intestinal and cutaneous involvement is described in a 70-yr-old woman. One of the neurogenic tumors with ganglionic cells apparently became transformed into a carcinoid composed of enterochromaffin cells. No distinct border was observed between the carcinoid and the underlying ganglio-neurofibroma. Nests of carcinoid tumor cells were intermingled with the neurogenic tumor tissue. A concomitant rise in plasma catecholamines and immunoreactive serum parathyroid hormone levels suggests the possibility of a multiple endocrine adenomatosis syndrome. The findings in this case support the theory that the enterochromaffine cell system of the gastrointestinal tract and the cells involved in uptake and decarboxylation of amines and amine precursors have a common origin within the neural crest.

0405 CHRONIC IDIOPATHIC INTESTINAL PSEUDO-OBSTRUCTION WITH MALABSORPTION, A SCLERODERMA-LIKE DISORDER. *(E.)* Lukie, B. E.; Sanders, M. G. (Toronto Western Hosp., Canada). *Can. Med. Assoc. J.* 15(2):1222-1227, 1973.

Intestinal pseudo-obstruction occurred in a 76-yr-old man who presented with a 6-yr history of vomiting and abdominal pain and a 1 1/2-yr history of diarrhea. Investigation demonstrated aperistalsis of the lower esophagus and an unresponsive atonic small intestine. Marked malabsorption was present and appeared to be caused by intestinal bacteria overgrowth resulting from the hypomotility. No definite abnormality was found in the autonomic nervous system. Although this disorder is markedly similar to scleroderma involving the gastrointestinal tract, only minimal fibrosis of the bowel musculature was evident at autopsy, and the neural components appeared to be intact. These findings suggest that the basic disorder may be one of smooth muscle dysfunction. Other known causes of pseudo-obstruction, including intestinal amyloidosis and gluten-sensitive enteropathy, could not be demonstrated.

Malabsorption

0446 HISTOCHEMICAL STUDIES OF THE MUCOSA OF THE SMALL INTESTINE IN IMPAIRED ABSORPTION SYNDROMES IN CHILDREN. *(E.)* Jonek, J.; Hager-Malecka, B.; Pawelek-Krombholz, D.; Sonta-Jakimczyk, D. (Inst. Biol. Morphol., Katowice, Poland). *Fol. Histochem. Cytochem.* 11(1):33-40, 1973.

The localization of acid and alkaline phosphatases, adenosine triphosphatase, and gamma-glutamyl transpeptidase activities was studied in mucosal biopsies from the small intestine of healthy children and in 14 children with malabsorption. In the controls these enzymes were most active in enterocytes in the apical parts of the villi. In children with malabsorption, the reaction for alkaline phosphatase and ATPase occurred in the so-called third zone of activity of the villus; this probably was connected with damage to the cell organelles with ensuing impairment of absorption and intracellular digestion processes. Gamma-glutamyl transpeptidase was slightly less active in sick than in healthy children. This decrease, however, was independent of the degree of injury to the cells of the absorption surface. These results suggest that morphological elements of the cell become damaged in malabsorption. This is associated with a decrease in the activities of several enzymes indispensable for most metabolic processes, including the absorption and digestion of food. It also seems likely that, as the damaging factors recede, the absorption surface regains its normal state as evidenced by normal histochemical reactions.

0447 INTESTINAL PERFUSION STUDIES IN TROPICAL SPRUE. I. TRANSPORT OF WATER, ELECTROLYTES, AND *d*-XYLOSE. *(E.)* Corcino, J. J.; Maldonado, M.; Klipstein, F. A. (Trop. Malabsorption Unit, Univ. Puerto Rico, San Juan). *Gastroenterology* 65(2):192-198, 1973.

Segmental jejunal perfusion studies were performed to assess water, sodium, chloride and *d*-xylose transport in 10 carefully selected patients (aged 15-67 yr) with untreated tropical sprue who had diarrhea for at least 1 month prior to and at the time of perfusion, and in 8 control subjects. All of the patients with tropical sprue were in a net secretory state in regards to water, sodium, and chloride as compared with control subjects. Of the 10 patients, 6 had steatorrhea and 5 had a low serum albumin Vitamin B_{12} absorption was impaired in all patients. *d*-Xylose absorption was lower in patients with tropical sprue (4.8 mg/hr/cm) than in controls (14.1 mg/hr/cm). By analysis of combined data from controls and patients with tropical sprue, a significant correlation was demonstrated between the absorption of xylose as measured by the segmental perfusion technique and 5-hr urinary xylose excretion as well as the peak serum xylose level obtained with a standard xylose absorption test utilizing a 25-g dose of xylose. The net secretory state for water, sodium, and chloride observed in patients with tropical sprue may be relevant to the pathogenesis of the diarrhea seen in this syndrome. Contamination with coliform bacteria occurs in tropical sprue, and certain of these organisms have been shown to produce enterotoxins. Whether these enterotoxins account fully for the derangements in water and electrolye transport found in patients with tropical sprue remains undetermined.

0448 ACQUIRED HYPEROXALURIA WITH REGIONAL ENTERITIS AFTER ILEAL RESECTION. ROLE OF DIETARY OXALATE. *(E.)* Stauffer, J. Q.; Humphreys, M. H.; Weir, G. J. (Naval Hosp., Great Lakes, Ill.). *Ann. Intern. Med.* 79(3):383-391, 1973.

Urinary oxalate excretion was measured in 11 patients (9 males and 2 females, aged 21-73 yr) with inflammatory bowel disease involving the terminal ileum. Of the 11, 6 patients had minimal or no resection of terminal ileum and 6 other patients had resections greater than 30 cm; 1 patient was studied before and after resection. Basal urinary oxalate excretion was normal in those with minimal or no resection, but was significantly elevated in the other group. Treatment with oral cholestyramine, caused urinary oxalate excretion to fall promptly to within the normal range in the group with extensive resection, but remained unchanged in the other group. Of 6 patients 5 had severe, explosive, watery diarrhea, which was dramatically reversed by cholestyramine. Hyperoxaluria in 2 patients was reversed when oxalate was removed from the diet. *In vitro* studies showed that cholestyramine binds oxalic acid. These data suggest that the mechanism of acquired hyperoxaluria in patients with ileal resection is related to enhanced absorption of dietary oxalate.

0449 LACTOSE-FREE MEDIUM-CHAIN TRIGLYCERIDE FORMULAS IN SEVERE MALNUTRITION. *(E.)* Graham, G. G.; Baertl, J. M.; Cordano, A.; Morales, E. (Sch. Med., Johns Hopkins Univ., Baltimore, Md.). *Am. J. Dis. Child.* 126(3):330-335, 1973.

A lactose-free medium chain triglyceride casein formula (Lactose-Free Portagen) was used in the successful management of 4 boys (aged 23.3-38.8 months) with kwashiorkor and 3 infants (2 males and 1 female, aged 5.1-16.5 months) with persistent hypoalbuminemia, 2 of whom had associated infections. A second formula (Pregestimil), based on a casein hydrolysate and medium-chain triglycerides with dextrose as a major carbohydrate, was used successfully in 5 infants with severe marasmus, 1 with kwashiorkor, and 5 with marasmus, severe diarrhea, and infection. Since about half of the children with Kwashiorkor had decreased lactose tolerance, the absence of lactose was of definite benefit. It is suggested that the dextrose benefited some of the sickest infants, but this was not proved. No evidence of sucrose intolerance or poor digestion of protein was found.

0450 CYSTIC FIBROSIS AND COELIAC DISEASE: COEXISTENCE IN TWO CHILDREN. *(E.)* Good-child, M. C.; Nelson, R.; Anderson, C. M. (Inst. Child Health, Univ. Birmingham, England). *Arch. Dis. Child.* 48(9):684-691, 1973.

Cystic fibrosis was diagnosed in 2 unrelated female infants aged 14 weeks and 10 months, resp., who were found subsequently to suffer from celiac disease as well. Both children are responding well to dietary gluten withdrawal and to conventional treatment for cystic fibrosis. It is suggested that cystic fibrosis, particularly in a child with a high risk HL-A phenotype, may predispose to the development of celiac disease. Therefore, jejunal biopsy may be a useful investigation in the occasional child with cystic fibrosis who presents with unusual features, or who fails to thrive as well as expected on regular therapeutic measures.

0451 NEUROLOGIC MANIFESTATIONS IN TROPICAL SPRUE. A CLINICAL AND ELECTRODIAGNOSTIC STUDY. *(E.)* Iyer, G. V.; Taori, G. M.; Kapadia, C. R.; Mathan, V. I.; Baker, S. J. (Christian Med. Coll. Hosp., Vellore, India). *Neurology* 23(9):959-966, 1973.

Malabsorption syndrome caused hospitalization of 24 patients (14 males and 10 females, aged 10-51 yr), all diagnosed as having tropical sprue. Fatigue and weakness were frequent complaints. Of the 15, 8 had obvious muscle wasting, 1 had tetany. Paresthesias were present in 6 patients. Mental changes of bradyphrenia, defective recent memory, and emotional lability were noted in 3 patients. Night blindness occurred in 5. Although the means of the distal latencies for the median, ulnar, and lateral popliteal nerves were slightly higher in sprue patients than in controls, the difference was significant only for the ulnar nerve. Peripheral neuropathy was detected in 8 patients. Dysrhythmia of 4 to 5 cps mainly in the frontal and temporal regions bilaterally was noted in 5 of 21 patients so tested. On needle electromyography, 10 patients showed a myopathic pattern. All these patients, except 1 who suffered from acute combined degeneration, responded well to treatment.

0452 DEMONSTRATION OF AN INACTIVE ENZYME ANTIGEN IN SUCRASE-ISOMALTASE DEFICIENCY. *(E.)* Dubs, R.; Steinmann, B.; Gitzelmann, R. (Childrens Hosp., Zurich, Switzerland). *Helv. Paediatr. Acta* 28(3):187-198, 1973.

A specific antibody against human sucrase-isomaltase was obtained from guinea pigs and used to identify the enzyme in epithelial cells of the small intestinal mucosa by indirect fluorescent staining. Human sucrase-isomaltase was thus visualized for the first time. The investigation was conducted using 6 children with sucrose intolerance due to hereditary sucrase-isomaltase deficiency. In all 6, immunofluorescence demonstrated the presence of the enzyme. The intensity of fluorescence varied markedly between patients and between areas of observation. In spite of fluorescence, lack of enzyme activity was complete in some patients. Thus, it is suggested that the structural alteration of the enzyme was such that complete inactivation resulted. Only partial correlation was noted between the intensity of fluorescence and the residual enzyme activity. Genetic heterogeneity was suspected in this small sample of sucrase-isomaltase deficient children.

LARGE INTESTINE

0471 THE EFFECT OF INTESTINAL PREPARATION ON FLUID AND ELECTROLYTE BALANCE. *(E.)* Irvin, T. T.; Hayter, C. J.; Warren, K. E.; Goligher, J. C. (Gen. Infirm., Leeds, England). *Br. J. Surg.* 60(6):484-488, 1973.

Measurements were made in 25 patients (16 males and 9 females, aged 59-83 yr) undergoing mechanical bowel preparation for surgery. At surgery, carcinoma of the colon or rectum was diagnosed in 12 patients, Crohn's disease in 1, and diverticular disease of the sigmoid in 12. Blood-volume measurements remained within normal limits after bowel preparation, and in 5 patients bowel preparation produced no change in total body exchangeable sodium, extracellular fluid volume, and plasma volume. Fluid and electrolyte balance studies in 11 cases showed that renal conservation of sodium occurred in the 24 hr preceding surgery, probably due to diminished dietary intake. Circulatory instability after the induction of anesthesia was commonly encountered, but in most cases this was not the result of preoperative dehydration. Little evidence was discovered to indicate that intestinal preparation in large bowel cancer results in significant fluid and electrolyte imbalance or that these patients are hypovolemic when anesthetized.

0472 NEOPLASTIC LESIONS OF THE COLON AND ANORECTUM IN BLACKS. *(E.)* Kolade, S. O.; Chung, E. B.; White, J. E.; Leffall, Jr., L. D. (Howard Univ. Cancer Res. Ctr., Washington, D. C.). *J. Natl. Med. Assoc.* 65(2):142-148, 1973.

A study was made of 394 neoplastic lesions of the colon and anorectal regions in black patients (102 males and 128 females aged 23-91 yr) treated over a 16 yr period. The clinical presentation is identical with that found in white patients. However, the incidence of adenocarcinoma in the young age group seems higher than that reported in whites. A ratio of 3.5:1 female to male is observed in patients of 30 yr and less. The mean ages for adenocarcinoma in male and females are similar to those observed in a predominantly white patient population. The adult incidence of mucinous adenocarcinoma, is double that of white populations. This colloid histological variety appears uniformly devastating regardless of age. Of the total number of adenocarcinomas in the series 3.9% occurred in the age group under 30 yr. The symptomatology in this young group is similar to that of adults, though it is not of any distinctive pattern. One patient had 2 synchronous primaries while 2 patients had 2 metachronous primaries. Carcinomas of other organs in addition to their colon lesions occurred in 2 patients. Thirteen polyps, 10 villous and 3 adenomatous, showed histological evidence of malignancy. Polyps accompanied the carcinomas in 19 cases. The 5-yr survival rate for followed patients who underwent curative surgery vas 50%.

)473 MESENTERIC INFARCTION. DIAGNOSTIC AND THERAPEUTIC ENIGMAS. *(E.)* Mattox, K. L.; Guinn,
. A. (Baylor Coll. Med., Waco, Texas). *Am. J. Surg.*
26(3):332-335, 1973.

owel infarction was studied in 38 patients (37 males
nd 1 female, median age 64 yr). Nonocclusive mesen-
eric ischemia in which the distal mesenteric arteries
nd veins were patent occurred in 20 patients, in 7
f whom noncritical stenosis of the proximal superior
esenteric artery caused by arteriosclerosis was a
actor. Occlusion of the superior artery with throm-
osis occurred in 9 patients, thrombosis of the mesen-
eric vein in 6, embolism of the superior mesenteric
rtery in 2, and arteriolar occlusion secondary to
olyarteritis in 1. Most patients presented with
odominal pain and distention, vomiting, diarrhea,
 gastrointestinal bleeding. In most of these pa-
ents, one of the commonly recognized causes pre-
pitated the condition, but in 16 of the 38 signi-
cant obstruction of the intestinal blood supply was
used by arteriosclerosis. It is suggested that
terial obstruction was a significant factor in these
tients, even though thrombosis of the major vessels
s usually absent. The only patients to survive in
is series were those with limited bowel infarction
d early adequate resection.

74 LATE COMPLICATIONS OF RADIATION-INDUCED DAMAGE TO THE GASTRO-INTESTINAL TRACT.
) Wolloch, Y.; Chaimoff, C.; Dintsman, M.
el Aviv Univ. Med. Sch., Israel). *Am. J. Proctol.*
(6):473-480, 1973.

e complications of radiation-induced damage to
 gastrointestinal tract are presented in 9 pa-
ents. Of these cases 8 were irradiated due to
cinoma of the uterus or cervix, while 1 was
adiated after nephrectomy for carcinoma of the left kidney. In 3 patients a colostomy was performed because of severe inflammation and narrowing of the rectosigmoid region. Another patient, with gangrene of the sigmoid, underwent resection of the damaged bowel and colostomy. She died several weeks later because of a pelvic abscess, the result of a perforation of the terminal ileum. At autopsy gangrene of the anterior rectal wall and of the lower segments of both ureters was also found. In the patient irradiated after nephrectomy, an operation performed 2.5 yr later, because of a suspected tumor of the splenic flexure of the colon, revealed a circular stricture induced by radiation. Four other patients are still receiving regular enemata of hydrocortisone, sedatives, and a low residue diet over a period ranging from 10 months to 3 yr and 10 months, because of persisting activity of the disease. Despite the large number of women who receive radiotherapy, only a small percentage suffer damage to the gastrointestinal tract. It appears that an individual sensitivity to the effect of irradiation exists, and that radiation induced damage to the gastrointestinal tract will appear in these more sensitive patients.

0475 PATHOLOGIC CHANGES IN THE COLON PRODUCED BY ANTHRAQUINONE PURGATIVES. *(E.)*
Smith, B. (St. Bartholomew's Hosp., London, England). *Dis. Colon Rectum* 16(6):455-458, 1973.

Pathologic changes produced by anthraquinone purgatives were studied in 13 specimens of colon from 12 patients. The morbid anatomic changes seen in the cathartic colon consist of three main features: damage and loss of the intrinsic innervation, atrophy of the smooth muscle coat, and melanosis coli. Changes seen in the myenteric plexus of the longstanding purgative addict consist of loss of neurons and replacement of the ganglia by Schwann cells. Macroscopic examination of the bowels showed them to be thin-walled.

LARGE INTESTINE

Ulcerative Colitis

0517 HEMORRHAGIC RECTOCOLITIS AND AUTOIMMUNE HEMOLYTIC ANEMIA. *(Fr.)* Carcassonne, Y. (Conception Hosp., Marseille, France). *Med. Chir. Dig.* 2(2):67-72, 1973.

Case reports are presented for 2 men, aged 21 and 23 yr, resp., who developed ulcerative colitis and, subsequently, hemolytic anemia, positive Coomb's tests, and splenomegaly. In the older patient the colitis responded to local treatment with corticosteroids and antibiotics, but anemia persisted and became more severe despite cortisone, blood transfusions, azathioprine, and anti-lymphocyte serum. Splenectomy became necessary and was followed by anoxic coma, severe respiratory infection, volvulus of the small intestine, dilatation of the stomach, and phlebitis. The anemia finally responded to iron protoxalate, and bilirubin levels returned to normal. The blood picture was satisfactory 1 yr later, but an exacerbation of the colitis occurred. The younger patient presented with joint symptoms and soon developed deformities of the hands and fingers. Repeated Waaler-Rose and latex tests for rheumatoid arthritis were negative. Diarrhea developed and ulcerative colitis was diagnosed 1 yr later. Splenomegaly and severe hemolytic anemia necessitated splenectomy, after which the anemia improved greatly but joint symptoms and melena persisted. From these findings and other reports in the literature it is concluded that these patients have an immunological disorder which favors the production of many antibodies and results in several diseases with different clinical features which have the same basis.

PANCREAS

0525 GASTROINTESTINAL RADIOLOGICAL FINDINGS IN CYSTIC FIBROSIS. *(E.)* Djurhuus, M. J.; Lykkegaard, E.; Pock-Steen, O. C. (Frederiksberg Hosp., Copenhagen, Denmark). *Pediatr. Radiol.* 1(2): 113-118, 1973.

A quantitative assessment was made of radiological gastrointestinal tract findings in 27 children (aged 1 1/2 to 16 yr) with cystic fibrosis and in 37 control patients (aged 2 to 13 yr). Compared with controls, the plicae and intestinal wall were wider in patients with cystic fibrosis; the maximal relative diameter of the intestine was greater; and transit time through the small intestine and proximal part of the colon was slower. Filling defects and spiculae were found in the colon and small intestine of nearly all, in the duodenum in about one-half, and in the stomach in one-fourth of the patients with cystic fibrosis. Diagnostically less important findings of decreased peristalsis, flocculation, fragmentation, segmentation, and a mottled appearance of the colon were observed more often in patients with cystic fibrosis than in controls. The spiculae were probably caused by intrusion of contrast medium into dilated crypts and the filling defects by the adjacent mucosa. These defects are rare in small intestinal disease and are thus of great diagnostic value for cystic fibrosis.

PANCREAS

Pancreatitis

0532 REPERCUSSIONS OF PANCREATITIS ON THE SPLEEN. *(Fr.)* Longo, O. F.; Mammana, L. A.; d'Agostino, J.; Huarte, C.; Nani, C.; Ferraria, A. (San Roque Hosp., Cordoba, Argentina). *Nouv. Presse Med.* 2(17):1125-1126, 1973.

In a 10-yr period, complications involving the spleen develcped in 7 of 26 patients with pancreatitis (12 with acute and 14 with chronic pancreatitis). Stasis resulted in splenomegaly in 3 cases (2 acute and 1 chronic). In 2 of these patients lymphography showed that contrast medium stopped flowing in the pancreatic region. Pseudocysts of the spleen, which occurred in 2 cases, were visualized by arteriography. Infections of the spleen were the cause of death in the 2 remaining patients; septic thrombosis was present at autopsy in 1. Complications of pancreatitis involving the spleen are attributed to the close relation between the pancreas and vascular and lymphatic parts of the spleen.

0539 PAPAVERINE - HEPATOTOXIC OR NOT? *(E.)* Drieman, P. M. (Camarillo State Hosp., Calif.). *J. Am. Geriatr. Soc.* 21(5):202-205, 1973.

A study was made of 30 patients (aged 52-88 yr) with organic brain syndrome in whom liver function tests showed normal results. These tests were performed before papaverine therapy and at 2, 4, 6, and 8 weeks after the start of this treatment. Papaverine was administered in 2 capsules every 12 hr, for a dosage of 600 mg/day. In 53% of the cases, therapy had ceased by the 6th week due to abnormal test results. At the conclusion of the study only 14 patients were still taking papaverine. During the study 18 patients reacted to the drug with abnormally high levels of alkaline phosphatase (the highest being 8.28 U); 4 patients (13%) had high SGOT and SGPT levels; and 6 (20%) had increased eosinophil counts. Nausea, vomiting, jaundice or dark urine did not occur in any of the cases. Tranquilizers were not taken by those patients in whom liver function was abnormal. It is suggested that hepatic hypersensitivity to papaverine may be the cause of the abnormal liver function test results.

0540 CONGENITAL FIBROSIS AND POLYCYSTIC DISEASE OF LIVER AND KIDNEYS. *(E.)* Thaler, M. M.; Ogata, E. S.; Goodman, J. R.; Piel, C. F.; Korobkin, M. T. (Dept. Pediatr., Univ. California, San Francisco). *Am. J. Dis. Child.* 126(3):374-380, 1973.

The presence of macrocysts and microcysts in kidneys and liver of a 15-yr-old girl with systemic and portal hypertension, thrombocytopenia, and hepatosplenomegaly was demonstrated by roentgenographic, surgical, and histologic investigations. Extensive deposits of collagen interposed between hepatocytes and proliferating biliary structures and distributed around dilated renal tubules were observed by ultrastructural studies. It is suggested that excessive and abnormally distributed connective tissue may represent the underlying defect in polycystic disease of the liver and kidneys and in congenital hepatic fibrosis.

0541 HEPATOTOXICITY OF METHOTREXATE IN THE TREATMENT OF PSORIASIS. *(E.)* Palmer, H. M. (Withington Hosp., Manchester, England). *Practitioner* 211(1263):324-328, 1973.

Methotrexate was given to 23 of 37 psoriatics (aged 33-68 yr) in interrupted daily oral dosage for up to 78 months. Total cumulative dosage ranged from 0.09 to 4.125 g. Abnormal liver biopsies were found in 16 (69.5%) of these patients: 3 (13%) were frankly cirrhotic, 4 (17.4%) showed mild to moderate hepatic fibrosis and 9 (31%) had varying degrees of fatty change. Of the cirrhotics 2 consumed excessive amounts of alcohol, the third admitted to taking alcohol only rarely. The liver damage did not correlate with either duration of therapy or cumulative dosage of methotrexate.

0542 PROFILES OF SERUM ISOENZYMES OF ALKALINE PHOSPHATASE IN HEPATOBILIARY DISORDERS USING CELLULOSE ACETATE ELECTROPHORESIS AND ORGAN-SPECIFIC INHIBITORS. *(E.)* Rhone, D. P.; Mizuno, F. M.; Gidaspow, H. (Illinois Masonic Med. Ctr., Chicago). *Ann. Clin. Lab. Sci.* 3(5):353-361, 1973.

The isoenzymes of alkaline phosphatase in the serum of 30 normal subjects (14 male and 16 female) and 90 patients with common hepatobiliary disorders were distinguished using electrophoresis on cellulose acetate. Diagnoses included nutritional cirrhosis (15), infectious hepatitis (16), serum hepatitis (9), metastatic tumors (23), obstructive jaundice (20), cholangitis (3), chronic hepatic congestion (1), hepatocellular carcinoma (1), granulomatous hepatitis (1), and adenocarcinoma of the colon metastatic to the liver (1). Physicochemical profiles of these mixtures of serum isoenzymes were determined using thermostability and organ-specific inhibitors (urea, L-phenylalanine, and L-homoarginine). Results of this investigation indicate that, in most cases, physicochemical testing is not sufficient alone to differentiate specific mixtures of alkaline phosphatase isoenzymes in the sera of healthy persons or in patients with hepatobiliary diseases. However, electrophoresis can identify individual components of a mixture of alkaline phosphatase isoenzymes in serum. It is suggested that densitometric scanning is the best method if quantitative data are required. It is also concluded that no hepatobiliary disorder studied in this series presents a particular physicochemical profile using heat inactivation and organ-specific inhibitors.

0543 HYPOTIBRINOGENEMIA ASSOCIATED WITH HEMANGIOMA OF THE LIVER. *(E.)* Martinez, J.; Shapiro, S. S.; Holburn, R. R.; Carabasi, R. A. (Cardeza Fdn. Hematol. Res., Philadelphia, Pa.). *Am. J. Clin. Pathol.* 60(2):194-197, 1973.

Blood clotting status was investigated in a 42-yr-old man with hemangioma of the liver, hypofibrinogenemia, a 9-yr-history of hepatomegaly, and no history suggestive of an increased bleeding tendency. Measurement of the plasma coagulation factors revealed decreased fibrinogen concentration, short euglobulin lysis time, prolonged thrombin time, and an increase of fibrinogen-fibrin split products. Platelet count, RBC survival, and plasma levels of Factors VIII, V, and prothrombin were within normal limits. ^{125}I-prothrombin metabolic values showed a normal prothrombin half-life and fractional catabolic rate. However, fibrinogen half-life was short and the fractional catabolic rate was increased. These studies suggest that this patient's hypofibrinogenemia might be caused by a fibrinolytic process unrelated to intravascular coagulation. Although the mechanism for activation of fibrinolysis is unknown in this patient, it is possible that a plasminogen activator may be released from endothelial cells of the hemangioma.

0544 DETERMINANTS OF SERUM ANTIPYRINE HALF-LIVES IN PATIENTS WITH LIVER DISEASE. *(E.)*

Branch, R. A.; Herbert, C. M.; Read, A. E. (Dept. Med., Univ. Bristol, England). *Gut* 14(7):569-573, 1973.

Antipyrine (1200 mg, p.o.) was used as a model drug to investigate the effects of liver disease on drug metabolism in 14 normal controls (aged 20-48 yr) and in 38 patients with liver disease including cirrhosis, chronic active hepatitis, acute hepatitis, and obstructive jaundice. A prolongation in antipyrine half-life was found in patients with liver disease. This increase was greater in patients with chronic liver disease than in those with acute, reversible pathology. Clinical complications of portosystemic anastomosis, portosystemic encephalopathy, and fluid retention did not affect antipyrine half-life. Patients with serum albumin below 3 g/100 ml or a prothrombin index below 80% had prolonged antipyrine half-life. Serum bilirubin, alkaline phosphatase, and aspartate transaminase did not correlate with prolonged half-life. The most prolonged half-life was associated with hypoalbuminemia and hypoprothrombinemia, suggesting that these changes were caused by defective protein synthesis of microsomal enzyme protein. This hypothesis was supported by demonstrating that the enzyme-inducing agents, phenobarbitone and prednisone, which increase the amount of microsomal enzyme protein, reduced the antipyrine half-life.

0545 CARCINOEMBRYONIC ANTIGEN IN SERUM IN DISEASES OF THE LIVER AND PANCREAS. *(E.)*

Khoo, S. K.; Mackay, I. R. (Walter and Eliza Inst. Med. Res., Melbourne, Australia). *J. Clin. Pathol.* 26(7):470-475, 1973.

Carcinoembryonic antigen was measured by microradioimmunoassay in whole serum and in serum extracted with perchloric acid in patients with benign and malignant diseases of the liver and pancreas. The level of detectability was 5 ng/ml. This level or greater was present in the serum of 50% of 115 patients with chronic diffuse liver disease, 64% of 14 patients with acute or chronic relapsing pancreatitis, 94% of 138 patients with cancer of the digestive system, and 3% of 230 controls. The incidence of levels of carcinoembryonic antigen of 5 ng/ml or more differed for various categories of chronic liver disease: 22% in 58 patients with active chronic hepatitis, 46% in 13 with primary biliary cirrhosis, 63% in 16 with hepatoma, 78% in 9 with cryptogenic cirrhosis, and 88% in 35 with alcoholic cirrhosis. Levels of carcinoembryonic antigen correlated with degrees of impairment of liver function as judged by BSP retention and serum levels of alkaline phosphatase and transaminase. In pancreatitis, 64% of cases had levels of carcinoembryonic antigen ranging from 5 to 20 ng/ml and in cancer of the pancreas 94% had levels above 5 ng/ml and 50% above 20 ng/ml. Although these results suggest that functional impairment of the liver is an important cause of increased levels of carcinoembryonic antigen, other causes must be invoked to account for the findings in pancreatitis, and the effects of inflammatory amage and cellular damage and regeneration remain o be assessed.

0546 CARBOHYDRATE METABOLISM IN PATIENTS WITH PRIMARY HEPATOCELLULAR CARCINOMA. *(E.)*

Vinik, A. I.; Pooler, W. (King Edward VIII Hosp., Durban, South Africa). *Clin. Sci. Mol. Med.* 45(3):387-396, 1973.

Responses to a glucose load (50 g, p.o.) and sodium tolbutamide (1 g, i.v.) have been compared in 13 Bantu patients (12 males and 1 female; aged 23-75 yr) with hepatocellular carcinoma and 10 control subjects. Patients with metabolic diseases affecting carbohydrate metabolism and those with a family history of diabetes, or ingestion of drugs were excluded from the control group. Lower basal plasma glucose and immunoreactive insulin concentrations were found in the hepatoma patients. Plasma insulin responses to glucose and tolbutamide were impaired, whether considered as the absolute concentrations or related to the plasma glucose concentrations as an insulinogenic index. Increased endogenous insulin sensitivity and hypoglycemic unresponsiveness as shown by a greater and more sustained fall in glucose concentration following i.v. administration of tolbutamide was also demonstrated in hepatoma patients. Basal growth hormone concentrations were within the normal range and did not rise paradoxically after glucose administration. These findings in hepatoma patients strikingly contrast with those seen in uncomplicated cirrhosis. The presence or absence of background cirrhosis with hepatoma did not alter these findings. This suggests that the tumor may be secreting a principle which either suppresses hepatic gluconeogenesis and/or enhances glucose utilization. The principle is not immunoreactive insulin, but may be other unidentified substances produced by the tumor which have an insulin-like effect.

0547 USE OF ORAL DDT IN THREE HUMAN BARBITURATE INTOXICATIONS: HEPATIC ENZYME INDUCTION BY RECIPROCAL DETOXICANTS. *(E.)*

Rappolt, R. T., Sr. (No affiliation). *Clin Toxicol* 6(2):147-151, 1973.

Three women, aged 18-39 yr, who had ingested moderate to massive (3000 mg) amounts of phenobarbital appeared to improve after p.o. administration of 5 g technical grade DDT in peanut oil. Too short a time elapsed before their recovery for true reciprocal detoxicants to induce hepatic enzymes. One patient was lost to follow-up, and the other 2 are alive and well. One patient had ataxia and anorexia for 5-6 days after barbiturate ingestion. It is suggested that none of these patients had ingested a potentially lethal dose of DDT and that the DDT, acting on a neuromuscular arousal capability of the central nervous system, backtitrated a sublethal dose of barbiturate.

0548 RETICULOENDOTHELIAL PHAGOCYTIC FUNCTION IN HUMAN LIVER DISEASE AND ITS RELATIONSHIP TO HAEMOLYSIS. *(E.)*

Cooksley, W. G. E.; Powell, L. W.; Halliday, J. W. (Dept. Med., Univ. Queensland, Brisbane, Australia). *Br. J. Haematol.* 25(2):147-164, 1973.

The rate of plasma disappearance of radio-iodinated microaggregated human serum albumin (^{125}I-MAA) was used to measure the reticuloendothelial phagocytic capacity in 57 patients with viral, alcoholic, or active chronic hepatitis (11), cirrhosis (42), or miscellaneous acute or chronic liver diseases (4). The relation of reticuloendothelial phagocytic capacity to splenic size, RBC survival, and splenic sequestration of RBC was analyzed. The reticuloendothelial perfusion was also measured using a tracer dose of ^{125}I-MAA. The reticuloendothelial phagocytic index was calculated and found to be increased in all forms of liver disease, independent of etiology or severity. Reticuloendothelial phagocytic capacity was normal in most forms of cirrhosis but was decreased in alcoholic cirrhosis patients, many of whom had diminished reticuloendothelial perfusion, associated with evidence of portal systemic shunting. A close relation between the reticuloendothelial phagocytic capacity and the reticuloendothelial perfusion was demonstrated. The relation between spleen size and reticuloendothelial phagocytic capacity in cirrhosis patients depended on the etiology of the disease. In 24 of 30 patients, the RBC survival was shortened. No correlation was found, however, between the degree of hemolysis and reticuloendothelial phagocytic capacity, reticuloendothelial phagocytic index, or splenic size. Splenic sequestration of RBC was seen in only 2 patients. In hepatic cirrhosis the reticuloendothelial system removes effete RBC presented to it, but is not primarily responsible for the mild hemolytic process.

0549 COPPER DYNAMICS IN WILSON'S DISEASE.

(E.) Osborn, S. B.; Walshe, J. M.; Williams, R. (King's Coll. Hosp., London, England). *Ann. Biol. Clin.* 30(4):391-396, 1973.

After i.v. injection of ^{64}Cu, liver clearance values were determined 100 times on 76 subjects. These consisted of 11 heterozygotes for Wilson's disease, 14 patients with untreated Wilson's disease, 42 patients with treated Wilson's disease, 9 with severe liver disease, 5 with primary biliary cirrhosis, 2 with hemachromatosis, and 17 normal controls. Although there were differences in mean liver clearance values between these groups, the differences were not significant. There was no tendency for liver clearance values to change with time in patients on whom determinations were made before and after institution of treatment. However, somewhat lower clearance values were obtained on inadequately treated patients. The way in which ^{64}Cu moves rapidly out of plasma after i.v. injection suggests that copper atoms do not diffuse between different body compartments, but undergo movement similar to the statistical "first-passage random walk".

0550 AUTOPSY FINDINGS IN THREE ORTHOTOPIC, ALLOGENEIC LIVER TRANSPLANTS IN ADULTS.

(Ger.) Bechtelsheimer, H.; Gedigk, P.; Muller, R.; Lie, T. S. (Pathol. Inst., Univ. Bonn, Germany). *Virchows Arch. Pathol. Anat.* 360(4):287-304, 1973.

Complications and gross and microscopic findings at autopsy are described for 3 patients who underwent orthotopic, allogeneic liver transplantation. All 3 patients received prednisone, azathioprine, and horse antilymphocyte globulin. The first patient, who survived for 202 days, developed transient signs of rejection 5 days after surgery and underwent a hepaticojejunostomy after 35 days for biliary tract necrosis. Signs of late rejection with vascular changes were observed at autopsy. Septicopyemia, caused by an abscess on the abdominal wall, and severe pyelophlebitis of the liver were the major complications. In the second patient, who survived for 6 days, primary ischemic damage of the homograft occurred from a prolonged period of ischemia at body temperature. Signs of acute rejection were found in the liver. The main complications consisted of suppurative cholangitis and pericholangitis, pulmonary embolism, and atelectasis of the lower right lung as a result of paralysis of the right side of the diaphragm caused by severing of branches of the phrenic nerve during surgery. Cardiac and respiratory failure due to pulmonary complications were the immediate cause of death. In the third patient, who also survived for 6 days, there was severe ischemic liver damage due to thrombosis of the hepatic artery with disseminated parenchymal necrosis. Signs of acute rejection were observed around areas of necrosis, but rejection was only mild in other areas of the parenchyma. Other complications included disturbances in bile drainage caused by surgical ligation of the cystic duct; this was associated with severe jaundice and hemorrhagic diathesis. The immediate causes of death were hepatic coma and renal failure.

0551 THE METABOLISM OF CHOLESTANOL, CHOLESTEROL, AND BILE ACIDS IN CEREBROTENDINOUS XANTHOMATOSIS.

(E.) Salen, G.; Grundy, S. M. (VA Hosp., East Orange, N.J.). *J. Clin. Invest.* 52(11):2822-2835, 1973.

Cholesterol and cholestanol metabolism was studied by sterol balance and isotope kinetic techniques in 3 subjects (2 females and 1 male, aged 32-46 yr) with cerebrotendinous xanthomatosis (CTX) and 11 other individuals. All subjects received diets free of cholesterol and cholestanol. After the i.v. administration of [1,2-^{3}H] cholestanol, the sterol was transported and esterified in plasma lipoproteins in a manner identical to cholesterol. The specific activity-time curves of plasma cholestanol conformed to 2-pool models in both the CTX patients and the control group. However, cholestanol plasma concentrations, total body miscible pools, and daily synthesis rates were 2 to 5 times greater in the CTX patients than in controls. The short-term specific activity decay curves of plasma [4-^{14}C] cholesterol also conformed to 2-pool models in both groups. However, in the CTX subjects the decay was more rapid, and daily cholesterol synthesis was nearly double that of the controls. Plasma concentrations and the size of the pool of exchangeable cholesterol were apparently small in the CTX subjects, and did not correlate with the large cholesterol deposits in tendon and tuberous xanthomas. Despite active cholesterol synthesis, bile acid formation was subnormal in the CTX patients. However, a rise in plasma cholestanol levels accompanied bile acid sequestration and greatly augmented fecal cholesanol outputs. In contrast, the administration of clofibrate (2 g/day) lowered plasma cholesterol levels 50% and presumably reduced synthesis in the CTX subjects. Plasma cholesterol concentrations and fecal steroid excretion did not change. These findings indicate that excessive tissue deposits of cholesterol and cholestanol characteristic of CTX are associated with hyperactive neutral sterol synthesis. The demonstration of subnormal bile acid formation suggests that defective bile acid synthesis may predispose to the neutral sterol abnormalities.

Hyperbilirubinemic States

0568 BILE ACID EXCRETION AFTER DISAPPEARANCE OF JAUNDICE IN INTRAHEPATIC CHOLESTASIS OF INFANCY.

(E.) Norman, A.; Strandvik, B. (St. Goran's Hosp. Children, Stockholm, Sweden). *Acta Paediatr. Scand.* 62(3):264-268, 1973.

In 12 cases of intrahepatic cholestasis of infancy the patients were reexamined 1-58 weeks after jaundice disappeared. All infants were clinically healthy, but 4 showed raised SGOT values from 100-158 U/ml and SGPT values from 100-190 U/ml. Cholic acid-24-^{14}C (1-7.5 µCi, i.m.) was administered and the isotope excretion in the urine and feces was subsequently investigated for 4 days. Most of the isotope was excreted in the feces. In 7 infants the urine contained less than 5% of the administered isotope and in the remaining 5 infants, the urine contained 9-26%. No unconjugated labeled cholic acid was excreted. After solvolysis and hydrolysis the major labeled compound was identified as cholic acid. No cholic or chenodeoxycholic acids were detected in the urine of 7 healthy infants used as controls. Cholic and chenodeoxycholic acids were excreted in the urine of all 12 patients at the time of reexamination, the total daily urinary excretion ranging from 0.6-3.7 µm. These results indicate that the bile acid excretion was impaired after regression of jaundice in infants who had had intrahepatic cholestasis.

0569 NEONATAL HYPERBILIRUBINEMIA IN CHINESE.

(E.) Yeung, C. Y. (Queen Elizabeth Hosp., Hong Kong). *Trop. Geogr. Med.* 25(2):151-157, 1973.

Of 1811 Chinese infants (1054 boys and 755 girls) with hyperbilirubinemia, ABO blood group incompatibility without hemolytic anemia was the cause in 414 (22.9%), erythrocyte glucose-6-phosphate dehydrogenase (G6PD) deficiency in 241 (13.4%), immaturity in 65 (3.6%), cephalhematoma in 40 (2%), and pyruvate kinase deficiency in 5 (0.2%). No specific cause could be identified in 1046 cases (57.9%), but 65% of these infants had symptoms suggestive of infections and a large percentage had enlarged livers or spleens. Kernicterus was diagnosed in 156 (8.6%) of the 1811 infants admitted for hyperbilirubinemia, and 31 (20%) of these had evidence of bilirubin encephalopathy at autopsy. In 68% of the infants who died of kernicterus, yellow staining was noted in both the basal nuclei and gray and white matter, which may account for the high incidence of spastic cerebral palsy, rather than classical athetosis and high-tone deafness, in Chinese survivors of kernicterus. The unusually high incidence of nonhemolytic hyperbilirubinemia in Chinese infants may be related to the use of Chinese herbal medicines by the mother in the last weeks of pregnancy. This hypothesis is supported by the relatively low percentage of immature infants with hyperbilirubinemia and the high incidence of hyperbilirubinemia among lower socioeconomic groups who are more likely to use herbal medicines. The latter fact may also be explained by the higher incidence of infections among families of lower socioeconomic status. The most common cause of hemolytic jaundice in these Chinese infants was G6PD deficiency which produced the most severe form of neonatal jaundice. The onset, 2-27 days after birth, was often preceded by exposure to moth balls or Chinese medicines (*Coptis chinensis or japonicum*, ox gallbladder, or thorn rose). The incidence of demonstrable sepsis was also significantly higher in these infants, suggesting a possible causal relation.

0570 USE OF BUCOLOME IN HYPERBILIRUBINEMIA.

(E.) Baba, K. (Nihon Univ., Sch. Med., Tokyo, Japan). *Paediatrician* 1(2):109-111, 1972/73.

Bucolome (5-n-butyl-1-cyclohexyl-2,4,6-trioxoperhydropyridine) was administered p.o. to 25 randomly selected, mature neonates; Coombs-positive infants and those born with asphyxia were excluded. These neonates received 100 mg/day of bucolome in 2 divided doses from day 1 to day 3 of life. Controls consisted of 20 newborns who did not receive the drug. Mean serum bilirubin levels in neonates treated with bucolome were 5.1 and 7.1 mg/100 ml on days 1 and 7, resp., whereas corresponding control bilirubin levels were 5.7 and 11.1 mg/100 ml, resp. Bucolome (600 mg/day, p.o. in 2 divided doses for 4 weeks) was also administered to an 8-yr-old boy with Gilbert's disease who had previously been treated with phenobarital (50 mg/day for 3 weeks). Serum bilirubin levels decreased but glucuronyl transferase activity was normal, which makes it unlikely that bucolome acts by enhancing hepatic glucuronyl transferase in Gilbert's disease. From results obtained in this study and from reports in the literature, it is suggested that bucolome reduces bilirubin levels in neonates by causing an increase in ligandin and/or glucuronyl transferase activity.

0571 PLACE OF PHOTOTHERAPY IN THE TREATMENT OF JAUNDICE IN THE NEWBORN.

(Fr.) Farriaux, J. P.; Wackenier, J. P.; Blanckaert, D.; Hongre, J. F.; Sauvage, R. (Univ. Hosp. Ctr., Lille, France). *Lille Med.* 18(4):403-414, 1973.

The effectiveness of phototherapy was studied in 150 newborns (65 girls and 84 boys) who developed jaundice within the first week after birth. In 52 cases the infants were premature or had a low birth weight. Jaundice was caused by ABO incompatibility in 28 cases and Rh incompatibility in 55; the etiology was unknown in 67 cases. Of these infants, 60 were exposed to blue light and 40 to white light; the remaining 50 were treated by classical methods but received no phototherapy. All treated infants were exposed to light for 24 hr/day for an average of 6 days until serum bilirubin levels decreased below 60 mg/liter. Bilirubin concentrations decreased more rapidly in the 2 groups receiving phototherapy than in controls. No significant differences were noted between the effects of white and blue light. When initial bilirubin values were above 80 mg/liter, more rapid decreases occurred with blue light, particularly in infants with Rh incompatibility. No differences were found between the effects of white and blue light at lower initial bilirubin levels. Phototherapy caused the most rapid decreases in bilirubin when initial levels were above 100 mg/liter. Exchange transfusions were required less often among newborns given phototherapy than among controls. Side effects of phototherapy included anemia, diarrhea, and cutaneous erythema, particularly in newborns exposed to blue light.

Nonviral Hepatitis and Hepatic Injury

0575 ACUTE HEPATIC NECROSIS OF HEPATITIS AND MUSHROOM POISONING. THE VALUE OF COAGULA-
TION TESTS IN THEIR DIFFERENTIATION, PROGNOSTIC AS-
ESSMENT AND PATHOGENESIS. *(E.)* Herold, R.;
traub, P. W. (Univ. Med. Clin., Zurich, Switzer-
and). *Helv. Med. Acta* 37(1):5-24, 1973.

he specific factor V assay and the prothrombin com-
lex assay were compared for prognostic evaluation.
lood coagulation and fibrinolysis was assessed in
5 patients (10 female and 5 male; mean age 21.4 yr)
ith severe hepatic failure due to *Amanita phalloides*
oisoning and 15 patients (12 female and 3 male; mean
ge 36.4 yr) with viral hepatitis and comparably low
inimal values for coagulation factors. The extent
r duration of prothrombin-complex depression once
e Quick value was below 30% did not affect the re-
lts. An excessive elevation of factor VIII was
ound during the phase of extreme prothrombin-com-
lex depression in the hepatitis group, but only a
oderate elevation in the group with poisoning. The
rombin time was significantly more prolonged in
e hepatitis group. Rapid depletion of clotting
ctors could not be entirely explained by mere ar-
est of synthesis, or by evidence of disseminated
travascular coagulation. Loss of plasma proteins
om the circulation is proposed as an alternative
chanism. Neither method was shown to be superior
the other.

76 JAUNDICE AFTER MULTIPLE HALOTHANE ANAESTHETICS ADMINISTERED DURING THE TREATMENT
CARCINOMA OF THE UTERUS. *(E.)* Davis, P.; Holds-
rth, C. D. (Roy. Infirm., Sheffield, England).
t 14(7):566-568, 1973.

er a 12-month period, hepatitis developed in 3 of
women with carcinoma of the uterus who received halothane anesthesia on 2 or more occasions. Of the 10 operations performed on these 3 women, aged 51-67 yr, all but 1, a vaginal hysterectomy, were minor. Two of the 3 received radiotherapy, but none had been given any other hepatotoxic drug or blood transfusions or had been exposed to infectious hepatitis. The onset of symptoms was marked by pyrexia 1-7 days after surgery; jaundice developed 2-3 days later and was accompanied by systemic disturbances. Liver function tests were typical of acute hepatic necrosis with a very high initial transaminase value which fell very rapidly, high serum bilirubin levels which fell more slowly, and moderate elevations in serum alkaline phosphatase activity. One patient had eosinophilia. A liver biopsy, performed in 1 case, showed a picture similar to that of acute viral hepatitis. Two of the 3 patients are alive and well 7 and 20 months, resp., after the development of hepatitis; the remaining patient died with renal failure 3 months after discharge. It is recommended that halothane be avoided for repeated frequent anesthesia as may be necessary for treatment of carcinoma of the uterus.

0577 STRUCTURAL AND FUNCTIONAL ABNORMALITIES OF THE LIVER IN PSORIASIS BEFORE AND DURING METHOTREXATE THERAPY. *(E.)* Almeyda, J.; Barnardo, D.; Baker, H.; Levene, G. M.; Landells, J. W. (London Hosp., England). *Br. J. Dermatol.* 87:623-631, 1972.

A study was made of 67 patients (39 males and 28 females, aged 16-77 yr) with severe psoriasis of from 1 to 47 yr duration. Of these 67, 25 were investigated before methotrexate therapy and 42 were examined during or after such therapy. Methotrexate dosage schedules were 2.5 mg p.o. 4 or 5 days/week; 12.5-25 mg p.o. once/week; or 20-40 mg i.m.

or i.v. at weekly or greater intervals. In the 42 patients treated for 3 to 80 months, more histological abnormalities were found than in 25 untreated patients with equally severe psoriasis. Of the treated patients, 3 had cirrhosis, all of whom were heavy drinkers, and 12 had fibrosis. None of the untreated patients had cirrhosis, but 4 had fibrosis. Only the cirrhotic patients showed clinical evidence of hepatic impairment. The incidence of histological abnormality increased with increasing cumulative dosage of methotrexate, but patients on weekly therapy had less abnormality than those on daily oral therapy. Of the 25 untreated patients, 14 were subsequently given the drug once/week for a mean of 23 months. Few additional histological abnormalities developed. In patients with socially and physically crippling psoriasis, the risk of significant hepatic damage through methotrexate therapy is low enough to be acceptable, providing supervision is thorough.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

0586 HEPATITIS AFFECTING HEMODIALYSIS AND TRANSPLANT PATIENTS: ITS CONSIDERATIONS AND SEQUENCES. *(E.)* Briggs, W. A.; Lazarus, J. M.; Birtch, A. G.; Hampers, C. L.; Hager, E. B.; Merrill, J. P. (Peter Bent Brigham Hosp., Boston, Mass.). *Arch. Intern. Med.* 132(1):21-28, 1973.

From March 1969 through July 1970, hepatitis developed in 14 patients undergoing dialysis, 14 who had received transplants, 9 medical personnel, and 1 patient's spouse. Dialysis patients were usually symptomatic; almost 1/2 were jaundiced, one died of hepatic failure, and persistence of Australia antigenemia was not the rule. The posttransplant patient who had been given immunosuppressants had a benign clinical course compared with both dialysis patients and contact cases. Azathioprine therapy adversely influenced the course of hepatitis in some posttransplant patients, and its temporary discontinuation was associated with rapid clinical and biochemical recovery and with a change from positive to negative test results for Australia antigen in 2 of 4 patients. Chronic Australia antigenemia occurred in 6 posttransplant patients, but only 2 of them had chronic elevation of SGOT X values. Intermittently elevated transaminase values occurred in 3 other posttransplant patients without a positive Australia antigen reaction.

0587 ELEVATION OF FACTOR VIII IN ACUTE LIVER NECROSIS. INFLUENCE OF PLASMAPHERESIS. *(E.)* Baele, G.; Vermeire, P.; Demeulenaere, L.; Barbier, F. (Dept. Internal Med., State Univ. Ghent, Belgium). *Digestion* 8(4):360-367, 1973.

The results of clotting tests during plasmapheresis in 3 female patients (aged 26-46 yr) with acute viral liver necrosis are reported. Elevated antihemophilic globulin (blood coagulation factor VIII) levels were found in all cases before plasmapheresis. During plasmapheresis, a decrease of factor VIII activity occurred in 2 cases. In the 3rd, persistently high factor VIII levels during several days of plasmapheresis suggest that disseminated intravascular coagulation may have been present. Increased synthesis or decreased catabolism of factor VIII must be considered when studying the mechanisms of the elevation of factor VIII in acute viral liver necrosis. Decrease in factor VIII during plasmapheresis may be due to a washout by donor plasma containing normal factor VIII concentrations. The return of factor VIII increased activity after cessation of plasmapheresis would support this suggestion. Extremely high levels of factor VIII may indicate an intense and sustained synthesis.

0588 A MAJOR EPIDEMIC OF INFECTIOUS HEPATITIS IN AN INSTITUTION FOR THE MENTALLY RETARDED.

E.) Matthew, E. B.; Dietzman, D. E.; Madden, D. L.;
Newman, S. J.; Sever, J. L.; Nagler, B.; Bouton, S.
1.; Rostafinski, M. (Infect. Dis. Br., Natl. Inst.
Health, Bethesda, Md.). *Am. J. Epidemiol.*
8(3):199-215, 1973.

he occurrence of 375 clinically manifest cases of
nfectious hepatitis among 3600 mentally retarded pa-
ients over a 6-month period was investigated. Only
employee developed clinically manifest hepatitis
uring the epidemic. The clinical to subclinical
atio of infection was approximately 2:1. The incu-
ation period averaged 29 days. Transmission was
robably from person to person by the fecal-oral
oute through direct contact or through fomites.
ttack rates were high, averaging 57% in a study
roup of 473 severely retarded patients. The attack
ates were low among wards of less retarded patients
no were capable of maintaining better personal hy-
iene. During the epidemic 2 deaths were attributed
hepatitis. Patients over 40 yr old or patients
nstitutionalized at this location for more than 18
had very low attack rates. The epidemic hepa-
itis was not related to the hepatitis B antigen
ustralia antigen). Administration of immune serum
lobulin initially failed to control the epidemic.
tack rates during a period in which no immune serum
obulin was given were similar. A controlled study
te in the epidemic demonstrated the effectiveness
immune serum globulin and the reasons for its
parent initial failure. No index cases were iden-
fied early in the epidemic. Immune serum globulin
s given on the day the first secondary case was
cognized and only prevented clinical disease which
uld have developed after 21 days. Administration
immune serum globulin prior to this proportionally
duced the time period over which secondary cases
re recognized.

39 INCIDENCE OF HEPATITIS AND AUSTRALIA ANTIGENEMIA AMONG LABORATORY WORKERS. *(E.)*

Grippo, G. A.; Hayashi, H. (Henry Ford Hosp.,
troit, Mich.). *Health Lab. Sci.* 10(3):157-162,
73.

uestionnaire survey was made to determine the
idence of hepatitis and Australia antigenemia among laboratory workers. A total of 51 laboratories with 731 personnel in the United States and 38 laboratories with 883 personnel in foreign countries responded. Of the 89 laboratories, 70 were research; 26 clinical; 24 blood bank, 12 renal unit; and 16 performed other functions. Some labs indicated 2 or more functions. The incidence of hepatitis (icteric and anicteric) among workers was 7.4% in the United States and 5.2% for all countries outside the United States. Australia antigenemia among laboratory workers was 2.5% in the United States and 2.7% in foreign countries. The combined rates of 6.2% in clinical hepatitis and 2.6% in Australia antigenemia reported in this survey were higher than those reported among normal populations. Since 16 of the laboratories (18%) conducted no laboratory tests for anicteric hepatitis among their personnel, the incidence of hepatitis could be higher. Of the 89 laboratories 67 (75%) were working with hepatitis-infected materials without inactivation before handling, and 41 of the 89 (46%) indicated no form of decontamination was used after handling infected materials. The survey indicates the need for: periodic examinations of lab personnel employing all available tests for anicteric hepatitis and sterilization of hepatitis-infected materials before and after handling. It is recommended that β-propiolactone and UV irradiation be used for sterilization since they inactivate hepatitis virus without altering the biological activity of Australia antigen.

0590 IMMUNOLOGICAL STUDIES OF AUSTRALIA ANTIGEN CARRIERS WITH AND WITHOUT LIVER DISEASES.

(E.) Nielsen, J. O.; Reinicke, V.; Dietrichson, O.; Andersen, V.; Thomsen, M.; Andersen, E. (Blegdam Hosp., Copenhagen, Denmark). *Clin. Exp. Immunol.* 15(1):9-16, 1973.

The cell-mediated and the humoral immune systems were examined in 2 groups of persistent carriers of Australia (Au) antigen. Group A included 11 blood donors with normal liver histology and without previous history of liver disease. Group B included 7 patients with an initial acute viral hepatitis verified by biopsy. Subsequent biopsies revealed progression to chronic persistent hepatitis in 3 cases, to chronic aggressive hepatitis in 3 and to a suspicion of chronicity in 1. The patients in group B had significantly higher serum concentration of IgM and significantly lower serum concentration of complement C4. No differences were found with respect to the presence of autoantibodies or the antibody response to vaccination with keyhole limpet hemocyanin. Delayed-type cutaneous reactions to 2,4-dinitrochlorobenzene, hemocyanin, and purified protein derivative (PPD) were equal in the 2 groups. The phytohemagglutinin-induced lymphocyte transformation was significantly lower in the group of patients with chronic hepatitis than in the healthy carriers, but none of the groups showed a statistically significant difference from a control group of 8 laboratory technicians. It is concluded that a general immunodeficiency state is not required for developing persistent Au-antigenemia. The slightly impaired T-cell response to PHA found in patients with persistent Au-antigenemia and chronic liver disease may be related to the liver disease rather than to the Au-antigen carrier state.

0591 CELLULAR IMMUNE REACTIONS TO HEPATITIS-ASSOCIATED ANTIGEN (HAA) AND HOMOLOGOUS LIVER-SPECIFIC PROTEIN (HLP) IN ACUTE HAA-POSITIVE HEPATITIS.

(Ger.) Knolle, J.; Meyer zum Buschenfelde, K. H.; Bolte, J. P.; Berger, J. (2nd Med. Clin., Johannes Gutenberg Univ., Mainz, Germany). *Klin. Wochenschr.* 51(23):1172-1174, 1973.

The leukocyte migration test was used to study cell-mediated immune responses to homologous liver-specific antigen (HLP) and hepatitis-associated antigen (HAA) in 51 patients within 3-8 weeks after the onset of HAA-positive acute hepatitis; 46 patients with HAA-negative acute hepatitis and 10 normal subjects served as controls. With HLP as the test antigen, leukocyte migration was inhibited in 13 of 46 patients with HAA-positive hepatitis. When HAA was used, leukocyte migration was inhibited in 21 of 33 patients who had HAA-positive hepatitis in the acute stage but later became HAA-negative; 5 of these patients showed stimulation. In contrast, leukocyte migration with HAA was inhibited in only 5 of 18 HAA-positive patients who became HAA carriers. This difference was statistically significant. Inhibition with both HAA and HLP was observed in only 9 patients. These results indicate that: (1) cellular immune reactions towards HAA occur more frequently in patients who later become HAA-negative; (2) there appears to be no correlation of delayed type immunity against HAA and HLP; and (3) intolerance to HLP can develop in HAA-positive hepatitis. These findings clearly show that hepatitis virus can cause development of autoimmunity.

0592 HEPATIC CIRCULATION IN YOUNG MALES WITH INFECTIOUS HEPATITIS STUDIED AT REST, DURING AND AFTER EXERCISE.

(E.) Lundbergh, P.; Strandell, T. (Roslagstull Hosp., Stockholm, Sweden). *Scand. J. Infect. Dis.* 5(2):155-157, 1973.

Hepatic vein catheterization was performed in 6 males (mean age 25 yr) with Australia antigen-negative infectious hepatitis and 11 healthy male volunteers. Serum bilirubin, SGOT, SGPT, and alkaline phosphatase values were elevated in most patients. At rest in the supine position the total hepatic blood flow estimated by the Bradley technique with indocyanine green was significantly higher in patients than in controls (2.37 and 1.37 liters/min, resp.). During supine bicycle exercise the absolute reduction of the hepatic blood flow was similar in patients and controls, with the patients on a significantly higher flow level. The difference between the wedged and free hepatic venous pressure in patients was 3.1 mm Hg before exercise and 3.8 mm Hg after exercise. The corresponding values for controls were 0.8 and 1.9 mm Hg, resp. The increased hepatic blood flow in patients with hepatitis may be caused by increased hepatic artery blood flow. The high pressures recorded after exercise from a wedged hepatic vein indicate a change in sinusoidal microcirculation which is probably due to a decrease in vascular resistance between the sinusoids and the hepatic artery. This dilatation should be of metabolic origin rather than caused by direct action of the virus. The apparent increase in hepatic artery flow does not rule out the possibility of changes in portal venous flow.

0593 SHIFT IN VIRAL STRAINS OF HEPATITIS B IN STOCKHOLM AS REFLECTED BY SUBTYPES OF HEPATITIS B ANTIGEN.

(E.) Magnius, L.; Berg, R.; Bjorvatn, B.; Svedmyr, A. (Ctr. Microbiol. Lab., Stockholm County Council, Sweden). *Scand. J. Infect. Dis.* 5(2):81-83, 1973.

Subtypes of hepatitis B antigen (HBAg) were determined in 72 patients with acute hepatitis hospitalized in Stockholm 1953-54 and in 202 patients seen during 1970. The relative incidence of HBAg-positive patients was similar in the 2 groups (43 and 49%, resp.). In 1953-54 subtype *ad* was found in 22 of 31 HBAg-positive patients and subtype *ay* in 2 patients. In 1970 only 12 of the 99 HBAg-positive patients had the *ad* subtype, while 75 had the *ay*. All 18 drug addicts among the HBAg-positive patients from 1970 carried the *ay* subtype and so did 90 of 95 HBAg-positive drug addicts attending the outpatient department during 1971-1972. Obviously a shift in predominating subtype has taken place from *ad* in 1953-54 to *ay* in 1970. Since only the *ay* subtypes is found in healthy carriers in Mediterranean countries and the Near and Middle East, it is suggested that tourists or drug addicts returning from these countries may be responsible for the shift in subtype.

0594 HYPOTHESIS TESTING: Gm ANTIGENS AND AUSTRALIA ANTIGEN.

(E.) Schanfield, M. S.; Fudenberg, H. H.; Polesky, H. F.; Perkins, H. A. (Univ. California Med. Ctr., San Francisco). *Nature (New Biol.)* 243(124):81-83, 1973.

Serum specimens from blood donors were classified as to the presence or absence of Australian antigen [Au (1)] and Australian antibody [anti-Au (1)] and typed for Gm allotypic markers. Individuals were considered homozygous for Gm allotypic markers if they were phenotypically Gm(ag), Gm(axg), or Gm(fb) and heterozygous for Gm antigens if they were Gm(agfb) or Gm(axgfb). Among the phenotypically Caucasian donors studied, no association between heterozygosity and homozygosity for Gm allotypic markers and Au(1) status was observed. Antibodies to Gm antigens were only detected when samples being typed for allotypic markers had a positive saline control, since low titers of antibodies to Gm antigens would not be detected by this method. Anti-Gm(a) was detected in 9 individuals, of which 6 were anti-Au-positive (4.2%)

and 3 were Au(1)-positive (1.8%). These findings were not signficantly different from the occurrence of anti-Gm(a) among Au(1)-positive or anti-Au(1)-positive individuals encountered in normal donors. Thus, there is no proven relation to immunization. Obviously, anti-Gm will normally occur in individuals who are homozygous for Gm antigens. Results of this study do not, therefore, support the hypothesis of previous investigations that persistent Au(1) is associated with Gm heterozygosity, while anti-Au(1) is associated with Gm homozygosity or anti-Gm. No significant differences in distribution of Gm phenotypes occurred between individuals with persistent Au(1) or with anti-Au(1), and there was no significant excess of anti-Gm among individuals with anti-Au(1) when compared with those individuals with persistent Au(1). If observations other than these are obtained, it is suggested that they may be due to the use of blood from patients who have received large numbers of transfusions at an early age.

LIVER AND BILIARY TRACT

Chronic Hepatitis

0602 DEPRESSION OF CELL-MEDIATED IMMUNITY IN OLD AGE AND THE IMMUNOPATHIC DISEASES, LUPUS ERYTHEMATOSUS, CHRONIC HEPATITIS AND RHEUMATOID ARTHRITIS. *(E.)* Toh, B. H.; Roberts Thomson, I. C.; lathews, J. D.; Whittingham, S.; Mackay, I. R. (Walter and Eliza Hall Inst. Med. Res., Melbourne, ustralia). *Clin. Exp. Immunol.* 14(2):193-202, 1973.

Cell-mediated immune response was studied by delayed ypersensitivity reactions to 5 antigens (*Candida*, umps, trichophyton, tuberculin, and streptokinase-treptodornase) injected intradermally and by lymphocyte transformation and humoral immune response was tudied by response to flagellin in 24 patients (18 omen and 6 men, aged 18-75 yr) with active chronic hepatitis and in 44 controls. At the time of testing, 7 of the patients with hepatitis were receiving prednisolone (5-20 mg/day) alone, 4 were receiving prednisolone (5-10 mg/day) + azathioprine (50-100 mg/day), and 1 was receiving cyclophosphamide (100 mg/day); 12 were not receiving drug treatment. The response of these patients to all 5 antigens was poor: a total of only 27 responses were recorded compared to 148 in the controls. Prednisolone had no effect on the number of positive reactions, but there were significantly fewer responses in patients given prednisolone + azathioprine. *In vitro* transformation of lymphocytes, both in unstimulated cultures and cultures stimulated with 100 μg of phytohemagglutinin, was significantly depressed in patients with chronic hepatitis. Weak delayed hypersensitivity responses were associated significantly with low titers of natural antibody to flagellin and with lower humoral immune responses to flagellin.

0603 CYTOPLASMIC FUSIONS BETWEEN LIVER PARENCHYMAL CELLS AND INFILTRATING CELLS IN CHRONIC AGGRESSIVE HEPATITIS.

(E.) Bassewitz, D. B.; Roessner, A.; Nauta, R.; Themann, H. (Dept. Med. Ultrastruct. Res., Westphalian Wilhelms Univ., Munster, Germany). *Virchows Arch.* [*Pathol. Anat.*] 359(4):309-313, 1973.

Lymphocytes and plasma cells have been demonstrated in the peripheral zones of lobules in 15 liver biopsies from patients with chronic aggressive hepatitis. In the region of contact between lymphocytes and parenchymal cells, the cell membranes were frequently not demonstrable, suggesting cytoplasmic fusion. However, when the goniometer is used, the cell membranes in this region can still be demonstrated at a certain tilt angle with respect to the electron beam. It is concluded that the presumed cytoplasmic fusions are frequently the result of superposition effects in projection.

0604 MEMBRANO-PROLIFERATIVE GLOMERULONEPHRITIS ASSOCIATED WITH PERSISTENT VIRAL HEPATITIS.

(E.) Myers, B. D.; Griffel, B.; Naveh, D.; Jankielowitz, T.; Klajman, A. (Meir Hosp., Kjar Saba, Israel). *Am. J. Clin. Pathol.* 60(2):222-228, 1973.

A 30-yr-old female had persistent viral hepatitis with chronic glomerulonephritis for 6 yr, the illness originally occurring during her first pregnancy. Following termination of the third pregnancy, she had marked hypertension, with exudate and hemorrhagic retinopathy, striking hepatomegaly, and moderate pitting pedal edema. Serum bilirubin was 0.5 mg/100 ml; SGOT, 10-20 U; and serum alkaline phosphatase, 24 I.U. The clinical picture was hematuria and nephrotic syndrome associated with hypertension and progressive renal failure prominent over the entire course of the disease. Electron microscopy showed mesangial hyperplasia with interposition of mesangial cytoplasm between endothelium and glomerular basement membrane. Kidney sections, when stained for IgG, serum complement component C'3, and Australian antigen (Au) in immunofluorescence tests, showed granular irregular deposits in the glomerular capillary loops, most pronounced at the periphery of the loops. A granular fluorescence was also observed in the mesangium when stained for Au and C'3. Serum complement components C'3 and C'4 could be detected in trace amounts only in the patient's serum using the Mancini radial immunodiffusion method in plates. It is suggested that immune complexes containing hepatitis virus are involved in producing glomerulonephritis and that a variety of pathologic glomerular responses may be evoked.

0605 THE INCIDENCE OF OXYPHENISATIN INGESTION IN ACTIVE CHRONIC HEPATITIS: A PROSPECTIVE CONTROLLED STUDY OF 29 PATIENTS.

(E.) Cooksley, W. G. E.; Cowen, A. E.; Powell, L. W. (Dept. Med., Univ. Queensland, Brisbane, Australia). *Aust. N.Z. J. Med.* 3(2):124-128, 1973.

A detailed inquiry was made into the laxative habits of 29 patients (22 females and 7 males) with active chronic hepatitis and a control group. In 5 of the 12 females over 30 yr old with active chronic hepatitis, regular oxyphenisatin ingestion was reported. This was highly significant when compared with 36 matched controls, 9 of whom regularly ingested laxatives, none of which contained oxyphenisatin. Also, in 2 of the patients who were challenged with the drug, an abrupt elevation in the serum bilirubin, and SGOT occurred within 24 hr of ingestion of a single tablet. Australia antigen was detected in the serum of only 1 patient. The results support an etiological role of oxyphenisatin ingestion in some patients with active chronic hepatitits, thus validating the action of the Australian Drug Evaluation Committee who recently withdrew the drug from the Australian market. Furthermore, the study demonstrated the predilection for middle-aged female patients.

0606 A POSSIBLE RELATIONSHIP TO TREATMENT BETWEEN HEPATITIS-ASSOCIATED ANTIGEN AND CHRONIC PERSISTENT HEPATITIS IN HODGKIN'S DISEASE.

(E.) Grange, M. J.; Erlinger, S.; Teillet, F.; Schlegel, N.; Barge, J.; Degott, C. (Beaujon Hosp., Clichy, France). *Gut* 14(6):433-437, 1973.

Hepatitis-associated (Australia) antigen (HAA) was detected in the sera of 16 (50%) of 33 patients with Hodgkin's disease; all of the patients had received the same treatment for approximately 2 yr, and had been in complete remission for at least 2 yr. The HAA-positive patients had significantly higher levels of serum SGPT (48 milliunits/ml compared with 18 milliunits/ml for negative patients) and significantly lower BSP clearance (0.10 compared with 0.13 for negative patients). Histological changes compatible with a diagnosis of chronic persistent hepatitis were found in the liver biopsies of 12 of the 16 HAA-positive patients and 5 of the 17 HAA-nagative patients. In 128 patients with Hodgkin's disease who have received various forms of treatment and who were studied at various stages of remission, HAA was found in the sera of 42 (33%). Tests for HAA repeated 4 months later in positive reactors of both groups showed persisting antigenemia. HAA was not present in the sera of any of 36 patients with Hodgkin's disease studied when the diagnosis was first made and before treatment had begun. These observations suggest that persistence of HAA and the presence of chronic persistent hepatitis were related to the treatment the patients had received rather than to the disease itself. A plausible hypothesis is that the acquisition and persistence of HAA are the result of treatment-induced impairment in the cell-mediated immune response.

0607 AUSTRALIA-ANTIGEN IN CHRONIC HEPATIC PATHOLOGY. *(Fr.)* Bondue, H. (Ixelles Hosp., Brussels, Belgium). *Acta Gastroenterol. Belg.* 36(6):282-301, 1973.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

0609 MESTEROLONE IN STEATOSIS AND CIRRHOSIS OF THE LIVER. *(E.)* Figueroa, R. B. (Inst. Invest. Clin., Universidad Nacional Mayor de San Marcos, Lima Peru). *Acta Hepatogastroenterol.* 20(4): 282-290, 1973.

Conventional liver therapy was conducted for 3-6 months in 33 chronic alcoholics (32 males and 1 female, aged 18-66 yr) and 16 nonalcoholics (8 male and 8 female, aged 25-51 yr) with chronic active liver disease. Of the 33 alcoholics, 11 had liver steatosis, 9 had liver steatosis and cirrhosis, and 13 had decompensated liver cirrhosis. In the nonalcoholic group, 14 patients and posthepatic cirrhosis, 1 had steatosis and hepatic granulomatosis, and 1 had tuberculosis and steatosis. Of the 49 patients, 30 received mesterolone (75 mg/day for 3 months) in addition to conventional therapy consisting of absolute banning of alcohol, bed rest for the first month, balanced diet, vitamin C (2 x 500 mg/day), and vitamin B complex (2 capsules/day) for 3-6 months. Results of the treatments showed that the clinical findings and liver function tests had improved to a much greater extent in the group receiving supplementary treatment with mesterolone. The improvement was particularly marked in patients with liver steatosis and those with liver steatosis and compensated liver cirrhosis. In both the alcoholic and nonalcoholic groups, an impressive improvement in general welfare was noted among those receiving mesterolone. The effect of mesterolone was poor in decompensated liver cirrhosis, due at least in part to the short duration of the treatment. No side effects were observed.

0610 PREDNISONE THERAPY OF ACUTE ALCOHOLIC HEPATITIS: REPORT OF A CONTROLLED TRIAL. *(E.)* Campra, J. L.; Hamlin, Jr., E. M.; Kirshbaum, R. J.; Olivier, M.; Redeker, A. G.; Reynolds, T. B. (Univ. Southern California Sch. Med., Los Angeles). *Ann. Intern. Med.* 79(5):625-631, 1973.

Of 45 hospitalized patients (aged 21-63 yr) with severe acute alcoholic hepatitis, 20 received prednisone therapy (0.5 mg/kg/day for 3 weeks and then 0.25 mg/kg/day for an additional 3 weeks). The remaining 25 patients served as controls. Mortality was 36% of prednisone-treated patients and 35% in controls. All deaths resulted from progressive hepatic failure, alone or in association with gastrointestinal bleeding or functional renal failure. The prednisone and control groups did not differ in duration of hospitalization, appetite, strength, rate of ambulation, or rate of improvement in serum bilirubin, SGOT, or prothrombin time. Serum albumin levels increased to a greater extent in the prednisone group, but this is attributed to a nonspecific effect of corticosteroid on albumin synthesis. Although the difference was not statistically significant, encephalopathic patients treated with prednisone survived longer than those in the control group. Although prednisone failed to induce any significant change in the clinical course of acute alcoholic hepatitis, further investigations may be justified to determine whether prednisone benefits patients who also have hepatic encephalopathy.

0611 MORPHOMETRIC STUDY OF THE ULTRASTRUCTURE OF HUMAN ALCOHOLIC FATTY LIVER. *(E.)* Oudea, M. C.; Collette, M.; Dedieu, P.; Oudea, P. (Hotel Dieu, Nantes, France). *Biomedicine* 19(10): 455-459, 1973.

Liver ultrastructure in 5 chronic alcoholics (males, aged 36-52 yr) without cirrhosis or liver cell necrosis was studied by a morphometric method. These subjects had consumed 100-250 g of ethanol/day for 10-20 yr, mainly as wine or beer. Comparison with liver tissue samples from 5 abstinent controls (males, aged 27-45 yr) showed a 34-fold increase in the volume density of fat droplets and a 20% increase in smooth endoplasmic reticulum surface density in alcoholics. The rough endoplasmic reticulum was unaltered. Mitochondrial volume density was increased (+23%) only when referred to fat-free cytoplasm unit volume, and there was no indication of increased mitochondrial mean volume. These results suggest that conspicuous mitochondrial alterations, such as those reported for severe forms of alcoholic hepatitis, are not found consistently in chronic alcoholism.

LIVER AND BILIARY TRACT

Cirrhosis

0614 PHYTOHAEMAGGLUTININ (PHA) INDUCED LYMPHOCYTE TRANSFORMATION AND TOXOPLASMA GONDII ANTIBODY STUDIES IN PRIMARY BILIARY CIRRHOSIS. EVIDENCE OF IMPAIRED CELL-MEDIATED IMMUNITY. *(E.)* MacSween, R. N. M.; Galbraith, I.; Thomas, M. A.; Watkinson, G.; Ludlam, G. B. (Western Infirm., Glasgow, Scotland). *Clin. Exp. Immunol.* 15(1):35-42, 1973.

Phytohemagglutinin induced dose-response lymphocyte transformation has been studied in 18 patients (17 female and 1 male; aged 30-71 yr) with primary biliary cirrhosis of from 1 to 11 yr duration. There was a marked reduction in responsiveness, particularly with low doses of phytohemagglutinin. These observations, together with the finding of a raised incidence (7%) of high titer *Toxoplasma gondii* antibody in primary biliary cirrhosis patients, are seen as evidence of impaired cell-mediated immunity in this disease. Results obtained in this study clearly show that *Toxoplasma* is not causally related to primary biliary cirrhosis.

0615 ANTIBODIES TO ESCHERICHIA COLI IN ALCOHOLIC AND NON-ALCOHOLIC PATIENTS WITH CIRRHOSIS OF THE LIVER OR FATTY LIVER. *(E.)* Prytz, H.; Bjorneboe, M.; Orskov, F.; Hilden, M. (Bispebjerg Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 8(5):433-438, 1973.

Agglutinin titrations were carried out on sera from 4 groups of patients with *Escherichia coli* O-groups. The patients consisted of 81 cirrhotics (37 alcoholics and 44 non-alcoholics), 16 with fatty liver (8 alcoholics and 8 non-alcoholics), 9 chronic alcoholics without liver disease, and 26 controls. Increased titers of antibodies to *E. coli* were found in liver cirrhosis and fatty liver: higher titers were found in cirrhosis. Higher titers of antibodies were found in alcoholic than in non-alcoholic liver disease. Differences in the immunoinhibiting ability of the liver in alcoholic and non-alcoholic liver disease may account for differences in the titers of *E. coli* antibodies. The increased frequency of *E. coli* infections in patients with cirrhosis may be due to functional defects in the reticuloendothelial system or to increased antigenicity of bacterial flora in the intestine.

0616 HYPERFIBRINOLYSIS IN CIRRHOSIS. *(E.)* Pises, P.; Bick, R.; Siegel, B. (Dept. Med., Univ. California, Los Angeles). *Am. J. Gastroenterol.* 60(3):280-289, 1973.

Bleeding esophageal varices were studied in 20 cases (17 male and 3 female, aged 31-60 yr) for coagulation factors, coagulation process, and fibrinolytic state. Evidence of hyperfibrinolysis was seen in 5 cases, as measured by active plasmin in 3 and protamine screening in 2. The failure of hepatic clearance of fibrinolytic activators, decreased or abnormal antifibrinolytic factors, or increases in tissue fibrinolytic activity must be considered as possible mechanisms for the pathogenesis of hyperfibrinolysis in cirrhosis.

0617 FACTORS AFFECTING PLASMA CLEARANCE OF [^{14}C] CHOLIC ACID IN PATIENTS WITH CIRRHOSIS. *(E.)* Kaye, M. D.; Struthers, Jr., F. E.; Tidball, J. S.; DeNiro, E.; Kern, Jr., F. (Univ. Colorado Sch. Med., Denver). *Clin. Sci. Mol. Med.* 45(2):147-161, 1973.

Clearance of ^{14}C-labeled cholic acid from the systemic circulation was studied in 6 normal subjects and patients with biopsy-proven primary biliary cirrhosis (1 case), postnecrotic cirrhosis (2 cases), and portal cirrhosis (5 cases). These 8 cirrhotics consisted of 5 men and 3 women, aged 25-65 yr. During fasting, the curve for disappearance of radioactivity from the serum was double-exponential in form during the first 100 min in both groups after ^{14}C-labeled cholic acid injection. During the early phase, cholic acid clearance was significantly more rapid and concentrations of conjugated and free bile were significantly lower in controls than in cirrhotics. Within 3 hr radioactivity had disappeared from the systemic circulation of controls, and neither i.v. cholecystokinin nor food ingestion had any effect on serum radioactivity. In contrast, radioactivity persisted in the serum of cirrhotics for at least 5 hr and, in 4 cases, for 24 hr. Of the 8 cirrhotics, 6 had "spontaneous" rises in serum radioactivity which began about 2 hr after ^{14}C-labeled cholic acid injection. Cholecystokinin or food given 4-8 hr after administration of cholic acid increased serum radioactivity as did reinfusion of duodenal juice into the upper intestine. Continuous aspiration of duodenal juice significantly reduced these rises. All rises occurred almost exclusively because of rises in conjugated bile acids. In cirrhotics, impaired bile acid clearance may result from inefficient hepatic extraction of bile acids, increased leakage of conjugated bile acids from hepatic cells, and shunting from portal to systemic circulation. The latter factor is probably responsible for elevated, fluctuating plasma bile acid concentrations in cirrhotics.

0618 AUSTRALIA ANTIGEN AND PRIMARY BILIARY CIRRHOSIS. *(E.)* MacSween, R. N. M.; Yeung Laiwah, A. A. C.; Busuttil, A. A.; Thomas, M. A.; Ross, S. K.; Watkinson, G.; Millman, I.; Blumberg, B. S. (Western Infirm., Glasgow, Scotland). *J. Clin. Pathol.* 26(5):335-339, 1973.

Sera from 64 patients (59 women and 5 men, aged 30-78 yr) with primary biliary cirrhosis were all negative for Australia (Au) antigen on immunodiffusion and immunoelectrophoresis. However, Au antigen was detected in sera from 10 patients (15.6%) but in only 2 (3.1%) of 64 age- and sex-matched controls by a radioimmunoprecipitation technique; this difference is highly significant. Of the 10 Au antigen-positive patients with biliary cirrhosis, 2 had received blood transfusions, 2 had undergone surgery, but the remaining 6 had no relevant history about a possible source of infection. Neither of the 2 controls had a history of jaundice or blood transfusions, and both had normal liver function tests. However, both had nursed family members with jaundice. Although radioimmunoprecipitation could be measuring some nonspecific blood constituent present in patients with primary biliary cirrhosis but not in controls, the higher incidence of Au antigen in biliary cirrhosis might mean that: (1) the antigen is involved in the genesis of this disease, (2) the disease is a result of antigen-antibody complex formation, (3) biliary cirrhosis is a disease which impairs immunity to viral hepatitis, or (4) the radioimmunoassay technique employed detects host material antigenically related to Au antigen. The radioimmunoassay also detected Au antibodies in sera from 6 patients (9.4%) and 5 controls (7.8%). Lymphocytes from 1 of 24 patients with primary biliary cirrhosis underwent transformation on stimulation with a serum rich in Au antigen. Failure to show delayed hypersensitivity to Au antigen in biliary cirrhosis could be a manifestation of the impairment of cellular immunity and could offer an explanation for apparent persistence of the virus in some cases.

0619 THE PRIMARY IMMUNE RESPONSE TO HAEMOCYANIN IN PATIENTS WITH PRIMARY BILIARY CIRRHOSIS. *(E.)* Fox, R. A.; Dudley, F. J.; Sherlock, S. (Roy. Free Hosp., London, England). *Clin. Exp. Immunol.* 14(4):473-480, 1973.

Both the humoral and cellular immune response to hemocyanin was measured in normal subjects and patients with liver disease including primary biliary cirrhosis (20 females and 2 males, aged 43-68 yr), other forms of cholestasis (biliary calculi, stricture, or neoplasm; 8 females and 2 males, aged 33-74 yr), and cryptogenic cirrhosis (15 females and 12 males, aged 14-65 yr). A sensitizing dose of 5 mg hemocyanin, injected s.c. in the right forearm, was followed on day 5 by intradermal injection of 100 μg hemocyanin in the left forearm. Significant differences in antibody titer were found 2 weeks after immunization and were highest in normal subjects, less in cryptogenic cirrhosis, and least in primary biliary cirrhosis.
The incidence of positive skin tests, indicating the development of delayed hypersensitivity to hemocyanin, was significantly less in patients with primary biliary cirrhosis and cryptogenic cirrhosis than in those with cholestasis or the normal subjects. It is suggested that the poor antibody response seen in primary biliary cirrhosis, could be related to impaired T cell function and hence lack of the T and B cell cooperation necessary for antibody formation to some antigens. The presence of delayed hypersensitivity to hemocyanin as measured by the skin test was compared to other tests of delayed hypersensitivity including the tuberculin skin test, dinitrochlorobenzene sensitization, and phytohemagglutinin-stimulated *in vitro* lymphocyte transformation. Of 20 patients with primary biliary cirrhosis the results of all 4 tests correlated in 9 but did not agree in the remaining 11. The importance of using a number of indices when assessing the degree of anergy of any one patient is evident.

0620 DYSCHROMATOPSIA WITH HEPATIC CIRRHOSIS: RELATION TO SERUM B_{12} AND FOLIC ACID. *(E.)* Rothstein, T. B.; Shapiro, M. W.; Sacks, J. G.; Weis, M. J. (Northwestern Univ. Med. Sch., Chicago, Ill.). *Am. J. Ophthalmol.* 75(5):889-894, 1973.

Laennec's cirrhosis was confirmed by liver biopsy in 16 male patients, aged 36-65 yr, who were subsequently evaluated for acquired dyschromatopsias, using the Farnsworth-Munsell 100-Hue Test. All subjects had histories of prolonged chronic ethanol intake and averaged 1 1/2 packs of cigarettes/day All patients with neurological symptoms associated with liver disease and/or alcoholism, those with a personal or family history of color blindness, those with ocular pathology, and those whose vision could not be corrected to 20/20 were excluded from this investigation. Of these cirrhotic subjects 88% had significant defects in color vision as compared to normal, healthy controls. No relation could be established between serum B_{12} levels and error score on the Farnsworth Munsell 100-Hue Test. However, 69% of the patients had abnormally low serum folic acid levels. Of these, 82% had error scores significantly different from the mean of the control population. Low serum folic acid levels may bear some relation to these acquired color-vision deficits. Decreased visual acuity need not precede defects in color vision as manifested on the Farnsworth-Munsell 100-Hue Test. If folic acid is a factor causing acquired dyschromatopsias, the results of this study indicate the deficit is not completely reversible.

0621 ENDOGENOUS INHIBITORS OF FIBRINOLYSIS IN CIRRHOSIS. *(Ger.)* Aschauer, R.; Holzknecht, F.; Platzer, S. (Med. Clin., Univ. Innsbruck, Austria). *Klin. Wochenschr.* 51(23):1170-1172, 1973.

Significant increases in α_2-macroglobulin and α_1-antitrypsin levels were found in 22 patients (16 men and 6 women) with cirrhosis. These increases were still evident when female patients and 6 patients receiving corticosteroids were excluded. Significant increases were also found in plasma urokinase inhibitor. After inhibitors of fibrinolysis had been removed, *in vitro* studies demonstrated that fibrinolysis was increased. Plasminogen activator was significantly increased, but plasminogen levels were significantly decreased. An increase in fibrinogen-fibrin degradation products provides further evidence of fibrinolysis activation. However, with the methods employed it could not be established whether this was caused by fibrinogenolysis or fibrinolysis, but the findings could be explained, at least partially, by impairment of the liver's ability to clear these products. Decreases occurred in antithrombin III, but it is not clear whether this is due to impaired synthesis or increased consumption. These findings do not rule out the possibility that endogenous fibrinolytic activity is inhibited in advanced cirrhosis by increases in inhibitors (α_2-macroglobulin, α_1-antitrypsin, urokinase inhibitor) although fibrinolytic activity is increased *in vitro* in a test system from which inhibitors have been removed. No explanation was found for the tendency to thrombus formation in cirrhosis.

0622 PLASMA VISCOSITY AND PORTAL HYPERTENSION IN PATIENTS WITH CIRRHOSIS. *(Ger.)* Leonhardt, H.; Bungert, H. J. (Steglitz Clin., Free Univ., Berlin, Germany). *Klin. Wochenschr.* 51(21):1043-1049, 1973.

Determinations of plasma viscosity, total protein, immunoglobulins, fibrinogen, cholinesterase, glutamate dehydrogenase, and γ-glutamyl transpeptidase were made on 32 patients (24 men and 8 women, aged 22-72 yr) with cirrhosis confirmed by laparoscopy and biopsy. All patients were evaluated for portal hypertension and esophageal varices. High plasma viscosity values were found in patients at the onset of portal hypertension, whereas low viscosity values were found in those with pronounced collateral circulation and esophageal varices. High plasma viscosity was most frequently associated with increases in IgG, while low plasma viscosity was associated with decreases in plasma fibrinogen concentrations. It is considered that these low viscosity values are causally related to decreases in plasma fibrinogen values, no matter whether the latter result from a latent intravascular coagulation or hyperfibrinolysis. Although it is not known whether disturbances in the synthesis of clotting factors by the liver also play a role, cholinesterase values, which are an indirect criterion of synthesis, were significantly decreased in all patients with cirrhosis, particularly in those with esophageal varices. Glutamate dehydrogenase and γ-glutamyl transpeptidase activities were increased, particularly in patients with portal hypertension and no varices.

0623 COMPARISON OF THE EFFECT OF VARIOUS AMINO ACIDS UPON THE BLOOD AMMONIA CONCENTRATION OF PATIENTS WITH LIVER DISEASE. *(E.)* Rudman, D.; Galambos, J. T.; Smith, III, R. B.; Salam, A. A.; Warren, W. D. (Emory Univ. Sch. Med., Atlanta, Ga.) *Am. J. Clin. Nutr.* 26(9):916-925, 1973.

The effect of 18 amino acids and urea on blood ammonia concentration was measured in 6 cirrhotic patients (5 males and 1 female, aged 34-62 yr) with Laennec's cirrhosis (5) or postnecrotic cirrhosis (1) and with a history of hepatic encephalopathy. Similar measurements were made on 9 normal subjects (aged 24-29 yr). Blood ammonia was determined before and at 2, 4, and 6 hr after ingestion of test material. Each preparation was tested at doses representing 0.00088 to 0.45 g N/kg body weight$^{3/4}$. Of the 18 amino acids, 10 increased blood ammonia, maximizing at 4 hr. The minimal effective dose of each amino acid elevating blood ammonia by 50 or 100 μg/100 ml at 4 hr was determined. Glycine was assigned an ammonigenic potency of 100. The 18 amino acids and urea were then ranked in three groups: potency 40 to 160, glycine, serine, threonine, glutamine, histidine, lysine, and asparagine; potency 9 to 25, leucine, alanine, valine, phenylalanine, isoleucine, tyrosine, and proline; and potency less than 7, arginine, aspartic acid, glutamic acid, tryptophan, and urea. The high potency of the first group may reflect the production of ammonia in the initial reaction of metabolic degradation (deamination or deamidation). The low potency of the other groups may be due to catabolism proceeding initially via transamination, with the amino groups entering the Krebs-Henseleit cycle via aspartic acid rather than ammonia. The hypothesis was supported by failure of neomycin to alter the oral ammonigenic protencies of glycine, serine, lysine, phenylalanine, leucine, and alanine; and by the appearance of a similar order of ammonigenic potencies for glycine, serine, threonine, glutamine, valine, phenylalanine, arginine, glutamic acid, and aspartic acid, whether tested by the p.o. or i.v. route.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

0630 SEX DIFFERENCES IN THE BILE ACID COMPOSITION OF HUMAN BILE: STUDIES IN PATIENTS WITH AND WITHOUT GALLSTONES. *(E.)* Fisher, M. M.; Yousef, I. M. (Dept. Med., Univ. Toronto, Canada). *Can. Med. Assoc. J.* 109(3):190-193, 1973.

The bile acid composition of human gallbladder bile was studied in 83 subjects (aged 20-75 yr). Of these 83 patients, 40 (20 males and 20 females) had no discernible hepatobiliary disease, and 20 men and 23 women had cholelithiasis. Of the 40 subjects with no discernible hepatobiliary disease, 25 had peptic ulcers and 9 had hiatus hernias. Bile acids were measured by combined thin-layer and gas-liquid chromatography. In the bile of patients without cholelithiasis the molar percent of cholic acid was significantly greater in men (52.69 vs. 33.44) while that of chenodeoxycholic acid was significantly greater in women (46.92 vs. 32.98). In the bile of patients with cholelithiasis the concentration of total bile acids was reduced in both sexes but there was no sex difference in the molar percent of any of the bile acids. The molar percent of chenodeoxycholic acid (both glycine and taurine conjugates) was reduced in women, while the molar percent of cholic acid (only the glycine conjugate) as reduced in men. Total lipids and total bile cids were very significantly decreased in lithogenc bile from both men and women. These findings suggest that there is a characteristic bile acid pattern in gallbladder bile from patients with cholelithiasis and that each sex has its own pattern.

0631 LONG-TERM RESULTS OF ROUX-EN-Y HEPATOCHOLANGIOJEJUNOSTOMY. *(E.)* Lane, C. E.; Sawyers, J. L.; Riddell, D. H.; Scott, Jr., H. W. (Vanderbilt Univ. Med. Ctr., Nashville, Tenn.). *Ann. Surg.* 177(6):714-722, 1973.

Hepatocholangiojejunostomy with a Roux-en-Y jejunal segment and the "fish-mouth" technique of managing the proximal hepatic duct was performed on 22 patients (14 women, 7 men, and 1 infant, aged 3.5 months to 80 yr) with high strictures of the hepatic bile duct. These patients have been followed for as long as 20 yr. In 17 cases the high stricture occurred after cholecystectomy. Of these 17 patients, 7 had concomitant common bile duct explorations while 10 had undergone only cholecystectomy. Thus, 80% of the patients apparently developed bile duct strictures from an injury sustained during a previous operation. Previous unsuccessful attempts to repair a bile duct stricture had been made in 12 patients. Recurrences had developed after end-to-end bile duct anastomoses (5 cases), plastic revisions of the common bile duct (4 cases), and choledochojejunostomy (3 cases). Two patients had undergone 4 previous operations each, and 2 patients had each had 7 previous attempts at repair of their stricture. Hepatocholangiojejunostomy gave acceptable results in 16 patients (73%). There was 1 postoperative death from peritonitis, gastrointestinal bleeding, and generalized sepsis. Reoperation was necessary in 5 patients (23%) who developed recurrent strictures. Other complications included upper gastrointestinal bleeding from stress ulcers (2 cases) and esophageal varices secondary to portal hypertension caused by biliary cirrhosis (2 cases); hepatic failure (1 case); cholangitis (5 cases); and subhepatic abscess (1 case). It is concluded that hepatocholangiojejunostomy is an effective operation for treatment of benign hepatic duct stricture when a mucosa-to-mucosa anastomosis either cannot be made or fails.

0632 MAN-MADE GALLSTONES: A NEW ENTITY FOLLOWING CARDIAC VALVE REPLACEMENT. *(E.)* Merendino, K. A.; Manhas, D. R. (Univ. Washington Sch. Med., Seattle). *Ann. Surg.* 177(6):694-704, 1973.

Mitral regurgitation secondary to rheumatic fever necessitated valve replacement in a 32-yr-old man. Postoperative jaundice and anemia developed with hepatosplenomegaly and lymphocytosis. Hemolytic anemia and hepatitis secondary to blood transfusion were considered responsible, but no evidence was found to support the latter diagnosis. Recurrent frequent attacks of cholecystitis developed, and gallstones were found. Persistent hemolysis plus mitral regurgitation forced replacement of the Gott valve. Subsequently, all evidence of significant hemolysis disappeared. The finding of 2 additional patients with similar histories initiated a study of the incidence of gallstones in patients with cardiac valve replacement. In 39 patients (31 men and 8 women, aged 21-66 yr) who had undergone prosthetic cardiac valve replacement a minimum of 18 months before, haptoglobin was absent in 32, decreased in 2, normal in 1, and unknown in 4; LDH was elevated in 36, normal in 2, and unknown in 1; and anemia was present in only 8. Gallstones were found in 12 (31%). Another group of 23 patients (10 men and 13 women, aged 25-70 yr) with valvular heart disease were studied prior to cardiac valve replacement. Haptoglobin was absent in 3, decreased in 4, normal in 9, and unknown in 7; LDH levels were elevated in 6, normal in 10, and unknown in 7; anemia was present in 5, absent in 16, unknown in 2. Gallstones occurred in 3 (13%).

0633 CHEMICAL COMPOSITION OF NEW ZEALAND GALLSTONES. *(E.)* Carlisle, V. F.; Tasman-Jones, C. (Dept. Med., Univ. Auckland, New Zealand). *Am. J. Surg.* 126(3):403-410, 1973.

Quantitative microanalysis of gallstones taken from 40 New Zealand patients shows that cholesterol gallstones predominate (88%). Analysis of multiple stones from the same patient showed the composition of these stones was similar. Analysis of individual stones in layers failed to reveal significant differences in composition. In stones of mixed composition, very high unidentified residues were found. Some stones found in this series support the theory that cholesterol stones are formed around a nucleus. Others supported the theory that cholesterol stones are first a colloidal mass with crystallization proceeding from the outside towards the center. No evidence was observed to suggest that cholesterol stones are produced by other than lithogenic bile from the liver. A more rigorous definition of cholesterol and mixed gallstones is deemed necessary so that the different environments under which each is formed may be noted and the type of stone present can be diagnosed by clinically accessible secretions.

0634 A CONSTANT BILE DUCT ANOMALY ENCOUNTERED DURING BILXIARY OPERATION. *(E.)* Murray, H. O. L. (no affil.). *Am. Surg.* 39(8):438-444, 1973.

In 309 consecutive cholecystectomies performed with operative cholangiography, 4 patients (2 males and 2 females, aged 20-62 yr) showed clinical evidence of an accessory bile duct. In 3 of the 4, the accessory bile duct joined the cystic duct. In the 4th case, the accessory duct joined the common hepatic duct immediately above the site of the former cystic duct. One patient also had situs inversus. It is suggested that a technique of cholecystectomy which permits visualization of the bile duct and environs during removal of the gallbladder permits recognition of the anomaly and should be used. Once an identity is made, the cystic artery is tied, the gallbladder is then dissected from the fundus down, exposing the gallbladder bed in which accessory ducts may be seen. In this series the incidence of accessory duct anomalies was less than 1.3% in operative cases. When bile leakage is suspected, a T-tube should be employed to drain the common bile duct. In the series 1 patient was found with no gallbladder, but choledocholithiasis was present; this is a very rare anomaly.

0635 ULTRASTRUCTURE OF THE HUMAN GALL-BLADDER EPITHELIUM IN CHOLELITHIASIS AND CHRONIC CHOLECYSTITIS. *(E.)* Fox, H. (Dept. Pathol., Univ. Manchester, England). *J. Pathol.* 108(2):157-164, 1973.

The gallbladder mucosa from 8 patients undergoing cholecystectomy for gallstones was examined under the electron microscope. All 8 samples showed some degree of nonspecific chronic inflammatory-cell infiltration. The mucosa ranged from morphologically normal in 3 cases to atrophic in 2. A mild degree of fibrosis of the lamina and the subserosa was noted in 5 cases. None contained cholesterol deposits or any evidence of neoplasms. In all cases the epithelial cells showed marked mucus secretory activity. Less common changes were a flattening of the columnar epithelial cells, with a loss of microvilli from their free surface, an excess of dark "pencil" cells, focal intestinal metaplasia and hypertrophy of the Golgi apparatus. Protrusion of cytoplasmic particles into the gallbladder lumen occurred in 2 cases, but degenerative changes were uncommon in the epithelial cells. It is suggested that in chronic gallbladder disease the mucosal epithelium tends to assume a secretory, rather than a predominantly absorptive, function.

0636 INCIDENCE OF GALLBLADDER DISEASE IN CANADA, ENGLAND, AND FRANCE. *(E.)* Plant, J. C. D.; Percy, I.; Bates, T.; Gastard, J.; Hita de Nercy, Y. (Wayne State Univ., Sch. Med., Detroit, Mich.). *Lancet* (7832):249-251, 1973.

A comparison was made of the number of gallbladder operations performed in 1961 and 1971 in 3 similar towns in Canada, England, and France. Although the incidence of cholecystectomy seems to be 6 times higher in Canada than in England or France, the rate of increase appears to be the same in all 3 countries. In Canada the incidence of cholecystectomy reached a maximum at 20-29 yr with a second maximum in the 40-49 yr group. In England maxima occurred at 40-49 yr and at 60-69 yr, while in France there was only 1 maximum in the 50-59 yr age group. In all 3 towns, but particularly in North America, a significant number of patients under 35 yr old were at or below normal weight. These findings suggest that dietary factors other than simple obesity are involved in the formation of gallstones. A comparison of dietary studies on these countries showed that prepared or processed food is consumed more in North American, to a lesser extent in England, and hardly at all in rural France. Since many food additives are powerful liver enzyme inducers, excessive consumption of these agents may be involved in gallstone formation.

0637 THE INCIDENCE AND SURGICAL SIGNIFICANCE OF CHOLELITHIASIS IN SICKLE CELL ANEMIA AND SICKLE CELL TRAIT. *(E.)* Golding, T. N.; Adeyemo, A.; Kurtz, L. (Freedmen's Hosp., Washington, D. C.). *J. Natl. Med. Assoc.* 65(5):410-414, 1973.

A retrospective study of cholelithiasis was made in 50 patients with proven sickle cell hemoglobinopathy (35 homozygous patients with sickle cell anemia and 15 heterozygotes for the sickle cell trait). Evidence of cholelithiasis was found in 13 of the 35 patients (37.14%) with sickle cell anemia and in 3 of the 15 (20%) who were heterozygotes for the sickle cell trait. These figures were much higher than the 10% generally accepted as the incidence of cholelithiasis in the normal population. The incidence of cholelithiasis was high (61.54%) among the 13 patients with anemia who were under 30 yr old and among males (8 of the 14 homozygous males had cholelithiasis). It is suggested that glucose-6-phosphate dehydrogenase deficiency, which is present in a large number of the patients with sickle cell trait, may contribute to hemolysis, with subsequent hyperbilirubinemia and cholelithiasis. Cholecystography should be performed on all patients with sickle cell trait who have recurrent abdominal pain since it is difficult to distinguish between acute cholecystitis and the painful crises of sickle cell anemia on the basis of clinical and laboratory evidence. The treatment of choice is elective cholecystectomy unless the patient is in an aplastic crisis.

0638 LIMY BILE. *(E.)* Hyland, G.; O'Connell, T. C. J. (St. Vincent's Hosp., Dublin, Ireland). *J. Irish Med. Assoc.* 66(13):354-357, 1973.

Episodes of severe epigastric pain with vomiting persisted for 4 months in a 54-yr-old woman. Diarrhea and vomiting with intermittent jaundice persisted for 3 months in a 67-yr-old man. In the first case, radiological examination revealed calculi in the gallbladder plus a fluid level which did not contract after administration of a fatty meal, a characteristic of limy bile. The wall of the gallbladder was severely hypertrophied, contained mixed stones surrounded by a white oily viscous tooth-paste like material. The paste consisted largely of calcium carbonate with traces of calcium and magnesium phosphate, while stones consisted of cholesterol with small amounts of bile salts, calcium carbonate, and phosphate. Chronic cholecystitis with Rokitansky-Aschoff sinuses was revealed. In the male patient, the gallbladder was delineated on plain x-ray as though the patient had a cholecystogram. Laparotomy revealed unresectable carcinoma of the head of the pancreas with limy bile in the common bile duct and gallbladder. No calculi were found. Analysis showed the bile consisted almost entirely of calcium carbonate with minimal quantities of bile salts. The lack of bile in the gallbladder of the first patient suggests that the duct was so obstructed so that bile could neither enter nor leave the gallbladder. Changes in pH, local calcium metabolism, and mucosal morphology are essential for the production of limy bile. Serum calcium levels are not of diagnostic or prognostic value.

0639 ESTIMATION OF CHOLESTEROL AND BILE ACID TURNOVER IN MAN BY KINETIC ANALYSIS. *(E.)* Quarfordt, S. H.; Greenfield, M. F. (Duke Univ. Med. Ctr., Durham, N. C.). *J. Clin. Invest.* 52(8): 1937-1945, 1973.

The kinetics of cholesterol and bile acid turnover were determined from an analysis of the biliary lipids after a single i.v. injection of labeled cholesterol. A compartmental model was designed for the system, and the fractional metabolic rates and fluxes were determined in 1 lean and 2 obese normal humans. Each of the normals converted about 3%/day of their rapidly miscible cholesterol pool to cholic acid and 1%/day or less to chenodeoxycholate. Cholate was catabolized at twice the rate of dihydroxy bile acids in these normal subjects. Of the normal subjects, 2 were fed corn oil with little change in their kinetic parameters from the control state. The other normal subject received cholestyramine

(16 g/day) which dramatically increased the bile acid flux with little change in neutral sterol catabolism. No deoxycholate was identified in the bile of a cirrhotic patient. The amount of cholesterol lost as neutral sterol and the amount of conversion to cholic acid were significantly less than in normal subjects. The daily neutral sterol and bile acid fluxes were fairly normal, due to the much larger size of the rapidly miscible cholesterol pool. The size of the cholic acid pool was significantly less than normal, while the fractional catabolic rate of chenodeoxycholate appeared to be more rapid than normal.

0640 ASCENDING CHOLANGITIS AFTER SUCCESSFUL SURGICAL REPAIR OF BILIARY ATRESIA. *(E.)*

Kobayashi, A.; Utsunomiya, T.; Ohbe, Y.; Shimizu, K. (Natl. Children's Hosp., Tokyo, Japan). *Arch. Dis. Child.* 48(9):697-703, 1973.

During a 5-yr period, 55 patients (35 females and 20 males) were diagnosed as having biliary atresia. Only 3 of the 55 cases were of the so-called surgically correctable type. In the other 52 cases, the proximal hepatic ducts were absent or rudimentary. The operation performed in all incorrectable cases was hepatic portojejunostomy. Of the correctable cases, 2 were treated with hepaticojejunostomy and the other with choledochojejunostomy in Roux-en-Y fashion. Good bile excretion after surgery was noted in 13 patients, 3 correctable and 10 incorrectable cases. In addition, hepatic portojejunostomy was successful in repairing 4 cases admitted with biliary atresia. The age of these 17 patients ranged from 4 weeks to 3 1/2 months. Of the 17, 8 (5 females and 3 males, aged 29-102 days at operation) developed ascending cholangitis 3 1/2 to 8 1/2 months after surgery. Total serum bilirubin ranged from 2.5-9.9 mg/100 ml; alkaline phosphatase, 36.8-83.4 Kind-King U; SGOT, 18-122 U; and SGPT. 2-96 U. Of these 8 cases, 4 received a two-stage procedure of hepatic portojejunostomy, 2 received a 1-stage operation, 1 had a choledochojejunostomy, and 1 a hepaticojejunostomy. Ascending cholangitis in these patients was characterized by repeated attacks of fever, reappearance of obstructive jaundice, raised erythrocyte sedimentation rate, leucocytosis with shift to the left, and anemia. The condition was often resistant to antibiotic therapy and was fatal in 3 cases in this series. No surgically uncorrected patient developed cholangitis, suggesting that patency of the intra- and extrahepatic biliary passages is essential for the development of the disease.

0641 THE EFFECT OF PSYLLIUM HYDROCOLLOID AND CHOLESTYRAMINE ON HEPATIC BILE LIPID COMPOSITION IN MAN. *(E.)*

Beher, W. T.; Schuman, B. M.; Block, M. A.; Lin, G. J.; Casazza, K. K. (Edsel B. Ford Inst. Med. Res., Detroit, Mich.). *Henry Ford Hosp. Med. J.* 21(1):21-30, 1973.

The effects of a mucoid, psyllium hydrocolloid, and an anion exchange polymer, cholestryamine, on the total cholesterol, total phospholipid, total bile salt, cholate, chenodeoxycholate, and deoxycholate concentrations of hepatic bile were determined in 6 post-cholecystectomy patients (5 females and 1 male). Bile was obtained by drainage through an indwelling T-tube, which was clamped except during collection. Psyllium hydrocolloid treatment (12 g/day, for 6-29 days) had little or no effect on the cholesterol or phospholipid concentration of hepatic bile. However, such treatment did increase the total bile salt pool by gradually increasing the concentration of deoxycholate. Cholestyramine treatment (12 g/day, for 8-12 days) had no significant effect on cholesterol, phospholipid or total bile salt concentrations. There was a significant increase in the tri- to dihydroxy bile salt ratio due to decreases in chenodeoxycholate and deoxycholate concentrations. Because of reductions in concentrations of taurine conjugates and compensating increases in glycine conjugates, the ratio of taurine to glycine conjugates decreased. It was concluded that changes effected by psyllium hydrocolloid may result in more stable bile micelles and greater cholesterol solubility. No definite conclusions were reached with regard to cholestyramine's effects.

0642 INFLUENCE OF AGE AND SEX ON GALLBLADDER EMPTYING INDUCED BY A FATTY MEAL IN NORMAL SUBJECTS. *(E.)*

Sacchetti, G.; Mandelli, V.; Roncoroni, L.; Montanari, C. (Med. Dept., Carlo Erba, Milan, Italy). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 119(1):40-45, 1973.

Normal gallbladder emptying induced by a fatty meal (2 egg yolks) was studied by oral cholecystography in 402 normal subjects (172 men and 230 women, aged 15-63 yr) without gastrointestinal disorders. Roentgenograms were made at intervals up to the 60th min after the meal. The radiopaque areas were measured planimetrically to provide a quantitative assessment of emptying. The emptying pattern was compatible with an exponential function. Emptying was faster in men. Emptying was significantly faster in men over 50 yr of age than in young people aged 15-20 yr. The emptying rate increased with age in men but not in women.

0643 ENDOSCOPIC AND RADIOLOGICAL REPRESENTATION OF ENTEROBILIARY FISTULAS. *(Ger.)*

Fruhmorgen, P.; Classen, M. (Med. Clin., Univ. Erlangen-Nurnberg, Erlangen, Germany). *Z. Gastroenterol.* 10(6):415-420, 1972.

Fiberendoscopy was used with radiological monitoring to visualize enterobiliary anastomoses in 15 patients. The anastomoses included 10 choledochoduodenostomies and 3 cholecystoduodenostomies which were all performed to alleviate obstructive jaundice. In addition, 1 patient had a cystoduodenostomy and 1 had a spontaneous cholecystoduodenostomy. In all cases laboratory findings were atypical or equivocal, and serum and urinary diastase activities were not significantly increased. Symptoms consisted of pain in the upper abdomen (10 cases), episodes of fever (4), jaundice (3), and partial ileus (1);

2 patients were asymptomatic at follow-up. In addition to fiberendoscopy and selective cholangiography, a radiological examination of the stomach and intestine was performed with barium contrast in 12 cases. It was demonstrated that symptoms were caused by chronic recurrent pancreatitis (6 cases), pancreatic lithiasis (2), pancreatic carcinoma (4), cholelithiasis (1), chronic aggressive hepatitis (1), and recurrent cholangitis (1). None of the anastomoses was stenotic and none required surgical revision.

0644 FREE GALLBLADDER PERFORATION AND BILE PERITONITIS WITHOUT PERFORATION. *(Ger.)*

Bussmann, J. F.; Loewe, K. R.; Kohler-Heurich, H. (Mannheim Clin., Univ. Heidelberg, Germany). *Langenbecks Arch. Chir.* 333(2):133-144, 1973.

Of 7338 patients who underwent cholecystectomies in a 22-yr period, 67 (40 women and 27 men, aged 36-86 yr; mean age 65 yr) developed bile peritonitis. Peritonitis was caused by spontaneous perforation of the gallbladder in 51 cases, iatrogenic perforation in 2, and traumatic perforation in 2; in 12 cases bile seeped through the gallbladder without any evidence of perforation. Perforation occurred in the gallbladder fundus in 30 cases, corpus in 7, and neck in 7; no information about the site of perforation was available in 11 cases. Of the 67 patients with gallbladder perforations, 38 had cholelithiasis, 9 choledocholithiasis with no stones in the gallbladder, and 8 had no stones; no information was available in 8 cases. Cholelithiasis was diagnosed in 3 patients who had bile peritonitis without gallbladder perforation: 2 had choledocholithiasis with no stones in the gallbladder, 6 had no stones, and no information was available in 1 case. With the exception of patients who had iatrogenic and traumatic perforations, all patients had ulcerative phlegmonous cholecystitis, generally involving the entire gallbladder. Vasculitis was observed in the gallbladders of 3 patients who had bile peritonitis but no gallbladder perforation. Bacterial cultures, made in 10 cases, showed that 4 had *Escherichia coli*, 1 *E. coli* + *Proteus vulgaris*, 1 *Salmonella paratyphi* B (a chronic carrier) and 1 *Micrococcus pyogenes aureus*; cultures were sterile in the remaining 3 cases. Surgery was performed on 66 of these 67 patients and consisted of cholecystectomy in 56 cases, revision of the bile duc ducts in 17, choledochoduodenostomy in 7, and suturing of the gallbladder in 1 patient with an iatrogenic perforation. Only abdominal drainage was performed on 9 patients who were in poor condition. Death from bile peritonitis occurred in 36 of the 67 patients (54%). The prognosis depended more upon the time elapsed from perforation to surgery than on the age of the patient. It is concluded that gallbladder perforation may be caused by ulcerative cholecystitis with or without cholelithiasis, by activation of trypsinogen in the bile ducts, or by an allergic reaction like the Shwartzman-Sanarelli phenomenon or localized vasculitis.

0645 GALLSTONES IN CHILDREN. *(E.)*

Newman, D. E. (Vancouver Gen. Hosp. Canada). *Pediat. Radiol.* 1(2):100-104, 1973.

The incidence, treatment, pathology, and etiology of cholelithiasis were studied in 133,400 children (aged 16 yr and under) from 1951-1970. In this 20-yr period, there were 19 cases of childhood cholelithiasis, 79% of which occurred in girls and 21% in boys. There is a general trend toward an increasing number of cases per year, particularly between the years 1965 and 1970. Cholelithiasis is most common in the preadolescent and adolescent age groups. The clinical findings of the 19 patients included: right upper quadrant or epigastric pain, nausea and vomiting, intolerance to fatty foods, previous appendectomy, epigastric or right upper quadrant tenderness, normal abdomen, acute abdomen, and jaundice. Radiology was the most useful diagnostic tool, resulting in a diagnosis of gallstones or changes highly suggestive of gallstones in all cases. Eighteen of the 19 patients were managed surgically with a cholecystectomy. Pathologic examination of the gallbladder revealed 2 patients with acute cholecystitis, 1 of whom had an empyema; 15 patients with chronic cholecystitis all of which were mild; and 2 patients who had normal gallbladders. The possible etiologic factors in childhood cholelithiasis include: hemolytic anemia, overweight, family history of cholethiasis, previous abdominal surgery or infection, and pregnancy.

0646 BILIARY-DUODENAL DYNAMICS IN MAN. CINERADIOGRAPHIC AND MANOMETRIC STUDIES FOLLOWING ADMINISTRATION OF DRUGS AND HORMONES. *(E.)*

Salik, J. O.; Siegel, C. I.; Mendeloff, A. I. (Sinai Hosp., Baltimore, Md.). *Radiology* 106:1-11, 1973.

Cineradiographic, 70-mm film and intraluminal manometric studies of the common bile duct and duodenum were undertaken on 53 patients with T-tubes 5-8 days after cholecystectomy, and 31 with intact gallbladders. These studies were made during a baseline period and again following administration of cholecystokinin (75 to 150 Ivy U, s.c.); the anticholinergic agents methscopolamine (1.0 mg, s.c.) and bellafoline (0.6 or 1.0 mg, s.c.); the smooth muscle relaxants nitroglycerin (0.6 mg, sublingual) and dicyclomine (20 mg, s.c.); and the analgesics morphine sulphate (1 mg/10 kg), meperidine (50 to 150 mg, parenterally) and morphine given in combination with cholecystokinin or atropine (1 mg, s.c.). Common duct flow generally correlated inversely with duodenal motor activity. Where discrepancies did occur, they could be explained by the fact that manometry measures intraluminal pressure alone, whereas cineradiography gives a composite picture of the tone, motility, and caliber of the structures examined. Autonomous sphincter of Oddi dampening or blocking of duodenal motor activity could account for a pattern in which duodenal activity was increased with a change in parallelism between the activity of the duodenum and the distal common duct. Questions remain on response of the atropinized hypotonic duodenum to morphine, which apparently affects different receptors or muscles. The method used in this study could evaluate various drugs acting on the choledochoduodenal segment.

0647 RADIOIMMUNOASSAY OF CONJUGATED CHOLYL BILE ACIDS IN SERUM. *(E.)* Simmonds, W. J.; Korman, M. G.; Go, V. L. W.; Hofmann, A. F. (Mayo Clin., Rochester, Minn.). *Gastroenterology* 65(5):705-711, 1973.

A rapid, sensitive, specific, and valid radioimmunoassay was developed for conjugated cholyl bile acids in unextracted serum. It uses antiserum, produced in rabbits, to cholylglycine coupled by amide linkage to bovine serum albumin. In a radioimmunoassay system, [^{3}H]cholylglycine and antibody reached equilibrium in 1 hr at 42 C. Bound antigen was precipitated by polyethylene glycol, and the free antigen in the supernate was determined by liquid scintillation spectrometry. The displacement curve was linear when the percentage binding of tracer was plotted against logarithmic increase of unlabeled cholylglycine from 5 to 80 picomoles. The antibody found cholylglycine and cholyltaurine similarly, but showed much less affinity for conjugated dihydroxy bile acids or unconjugated bile acids. Cholesterol and hormonal steroids were not bound. The final assay method used less than 0.1 ml of serum and was validated by showing close agreement between radioimmunoassay values and those determined by gas liquid chromatography. In 40 fasting normal subjects, serum levels of immunoreactive conjugated cholyl bile acids were less than 1 μM. This method should be useful for assessing hepatic function in health and disease. In assaying serum samples from a group of 32 patients with chronic hepatitis, a subgroup arose with serum bile acid values definitely above the normal range, but with normal bilirubin values. This suggests that serum bile acid determinations may be useful for detecting impaired liver function when the serum bilirubin level is normal.

0648 ORAL FIBROSCOPIC REMOVAL OF STONES FROM THE COMMON BILE DUCT. *(Ger.)* Deyhle, P.; Fumagalli, I.; Nuesch, H. J.; Holdener, F.; Siegenthaler, G. (Univ. Zurich Med. Sch., Switzerland). *Dtsch. Med. Wochenschr.* 98(41):1891-1892, 1973.

GENERAL

0663 AD LIBITUM ORAL GLUCOSE-ELECTROLYTE THERAPY FOR ACUTE DIARRHEA IN APACHE CHILDREN. *(E.)* Hirschhorn, N.; McCarthy, B. J.; Ranney, B.; Hirschhorn, M. A.; Woodward, S. T.; Lacapa, A.; Cash, R. A.; Woodward, W. E. (Johns Hopkins Univ. Sch. Med., Baltimore, Md.). *J. Pediatr.* 83(4):562-571, 1973.

Diarrhea caused hospitalization of 47 children (28 girls and 19 boys; 45 under the age of 2 yr). A recognized pathogen was found in the stool of 21% of the cases. Children who were strong enough to drink and had bowel sounds were generally able to take sufficient amounts of a hypotonic glucose-electrolyte solution appropriate to their requirements for volume replacement and maintenance. Clinically apparent volume depletion (present in 48% of the patients), moderate hypo- and hypernatremia, and acidosis were readily corrected. Children originally in shock (3) could drink the solution after rapid i.v. volume replacement. In 2 children with severe glucose intolerance, several days' use of a carbohydrate-free formula and broad-spectrum antibiotics brought about recovery. *Ad libitum* oral therapy is effective, comfortable, and inexpensive, and may reduce the morbidity and mortality rates of infantile diarrhea.

0664 THE EFFECT OF ESCHERICHIA COLI ENTEROTOXINS ON THE SMALL INTESTINE WITH OR WITHOUT DIRECT MUCOSAL CONTACT. *(E.)* Staley, T. E.; Jones E. W.; Smith-Staley, J. A. (Coll. Vet. Med., Oklahoma State Univ., Stillwater). *Am. J. Dig. Dis.* 18(9):751-756, 1973.

There was a progressive increase in intraintestinal fluid volume in rabbits after direct mucosal contact with 2 *Escherichia coli* enterotoxins. Also the mucosa continued to secrete for a 2-hr period despite flushing of the enterotoxin from the isolated loops. These enterotoxins are apparently bound tightly to the intestinal epithelial cell and the effect is sustained. In the intestinal loops not having direct mucosal contact with enterotoxin, the intraintestinal fluid volume remained relatively constant. These results indicated that enterotoxin in an isolated loop influenced the fluid movement in adjacent loops throughout the entire test period. Failure of the intestinal fluxes to return to normal after flushing of the intestinal loop may have been due to a failure to adequately bind enterotoxin or to an intestinal immunity.

0665 SERUM VITAMIN A, RETINOL-BINDING PROTEIN, AND PREALBUMIN CONCENTRATIONS IN PROTEIN-CALORIE MALNUTRITION. II. TREATMENT INCLUDING SUPPLEMENTAL VITAMIN A. *(E.)* Smith, F. R.; Goodman, D. W.; Arroyave, G.; Viteri, F. (Dept. Med. Columbia Univ., New York, N. Y.). *Am. J. Clin. Nutr.* 26(9):982-987, 1973.

The serum retinol transport system was studied in 8 Central American boys (18-65 months old) with marasmic kwashiorkor before and after treatment with protein, calories, and supplemental vitamin A. Serum concentrations of vitamin A, retinol-binding protein, and prealbumin increased significantly with therapy, as did concentrations of serum albumin and total protein and the creatinine-height index. During treatment highly significant correlation was observed between the levels of vitamin A, retinol-binding protein, and prealbumin, suggesting that diet therapy had a similar effect on retinol-binding holoprotein and prealbumin. No correlations were found between serum concentrations of vitamin A, retinol-binding protein, or prealbumin and the serum albumin concentration or creatinine-height index. Vitamin A, retinol-binding protein, and prealbumin concentrations generally reached a maximum after 20-40 days of treatment but decreased after 60-90 days, whereas serum albumin and total protein concentrations and the creatinine-height index increased progressively during therapy in almost all patients. It is concluded that factors other than the availability of amino acid and protein substrate influence serum retinol transport in protein-calorie malnutrition.

0666 SERUM VITAMIN A, RETINOL-BINDING PROTEIN, AND PREALBUMIN CONCENTRATIONS IN PROTEIN-CALORIE MALNUTRITION. I. A FUNCTIONAL DEFECT IN HEPATIC RETINOL RELEASE. *(E.)* Smith, F. R.; Goodman, D. S.; Zaklama, M. S.; Gabr, M. K.; El Maraghy, S.; Patwardhan, V. N. (Dept. Med., Columbia Univ., New York, N. Y.). *Am. J. Clin. Nutr.* 26(9):973-981, 1973.

Components of the plasma vitamin A transport system have been examined in 33 Egyptian children with varying degrees of protein-calorie malnutrition and in 15 sex- and age-matched controls. Classical kwashiorkor in 21 children (16 boys and 5 girls, mean age 1.8 yr) was associated with significantly decreased concentrations of serum retinol-binding protein, prealbumin, vitamin A, carotenoids, albumin, and total protein. After diet therapy, but without supplemental vitamin A, 11 patients with kwashiorkor had highly significant increases in concentrations of vitamin A, retinol-binding protein, and prealbumin by the end of the 2nd week with further increases occurring by the 4th week and were considered to be clinically cured. Vitamin A, retinol-binding protein, and prealbumin concentrations were comparable to or higher than those of the controls at discharge. In 6 children with marasmus (5 boys and 1 girl, mean age 1.5 yr) pretreatment vitamin A and retinol-binding protein concentrations did not differ significantly from controls. Highly significant correlations were observed between serum vitamin A, retinol-binding protein, and prealbumin concentrations during treatment of kwashiorkor. These findings suggest that the low serum vitamin A levels in kwashiorkor largely reflect a functional impairment in hepatic release of vitamin A, rather than vitamin A deficiency. This impairment results from defective hepatic production of plasma proteins, including plasma transport proteins for retinol, because of a limiting supply of substrate for protein synthesis. When dietary calories and protein supply the necessary substrate, hepatic production of plasma proteins increases, plasma retinol-binding protein and prealbumin concentrations rise, and consequently plasma vitamin A concentration increases.

0667 SERUM IMMUNOGLOBULIN E (IgE) CONCENTRATIONS IN PATIENTS WITH GASTROINTESTINAL DISORDERS. *(E.)* Brown, W. R.; Lansford, C. L.; Hornbrook, M. (Univ. Colorado Med. Ctr., Denver). *Am. J. Dig. Dis.* 18(8):641-645, 1973.

IgE concentrations, measured by radial immunodiffusion, were normal in 71 patients with giardiasis, amebiasis, chronic ulcerative colitis, regional enteritis, chronic liver diseases, or nontropical sprue. Concentrations were above the normal range in 2 of 7 patients infested with intestinal roundworms. IgE was undetectable in 2 patients with an associated deficiency of IgA and gluten-sensitive enteropathy and in 3 patients with generalized hypogammaglobulinemia, giardiasis, and malabsorption. This study of IgE in serum provides no evidence of activation of the IgE immunologic system in the disorders studied, other than in roundworm infestations. The findings suggest however, that IgE deficiency is common in immunodeficiency-related gut disorders, although the pathogenetic significance of the IgE deficit remains uncertain.

0668 SERUM IMMUNOGLOBULINS AND COPROANTIBODY FORMATION IN INFANTS AFTER ARTIFICIAL INTESTINAL COLONIZATION WITH ESCHERICHIA COLI 083 AND ORAL LYSOZYME ADMINISTRATION. *(E.)* Lodinova, R.; Jouja, V.; Wagner, V. (Inst. Care Mother and Child, Prague, Czechoslovakia). *Pediatr. Res.* (7):659-669, 1973.

The influence of oral colonization with nonenteropathogenic *Escherichia coli 083* and feeding with lysozyme in breast-fed and bottle-fed infants on the production of immunoglobulins and antibodies in serum and stool filtrates were studied. In colonized infants, *E. coli 083* was detected in the stool from the 2nd day after p.o. administration and predominated for up to 16 weeks. The serum antibody against *E. coli 083* increased the 4th week after colonization and remained higher than in controls until 16 weeks. At that age the antibody level did not differ from the bottle-fed control group. In breast-fed control subjects, however, the titer remained low. Immunoglobulin G (IgG) passively transferred from the mother decreased slowly and from the 12th week an increase, which was probably due to the infants' own production, was shown. In breast-fed control subjects, no decrease was noticed. Immunoglobulin A (IgA) level went up gradually from the 4th week in all groups of infants. The colonization and lysozyme administration did not significantly influence the serum immunoglobulin levels. Coproantibody formation was detected in colonized, artificially fed infants at 4 weeks and the maximum level persisted to 16 weeks. In breast-fed, colonized infants the coproantibody level was significantly higher between 2 and 6 weeks when compared with controls. Immunoglobulin M was detectable only in the bottle-fed colonized group, from the 4th to 16th week. Secretory IgA level in breast-fed, colonized, and control infants was high between 1 and 8 weeks. In bottle-fed, colonized infants IgA increased from the 4th week and remained significantly higher in the 6th, 12th, and 16th week when compared with control subjects. No IgG was found in stool filtrates of any group. No difference in the coproantibody response was observed between the lysozyme-fed and the artificially fed control groups. The artificial colonization induced a formation of secretory IgA. This effect was masked in the breast-fed infants because of passive transfer of this immunoglobulin. The lack of IgA in bottle-fed infants was substituted by active formation caused by artificial colonization.

0669 EFFECTS OF CYCLOHEXIMIDE ON THE RESPONSE OF INTESTINAL MUCOSA TO CHOLERA ENTEROTOXIN. *(E.)* Kimberg, D. V.; Field, M.; Gershon, E.; Schooley, R. T.; Henderson, A. (Harvard Med. Sch., Boston, Mass.). *J. Clin. Invest.* 52:1376-1383, 1973.

The interaction between cycloheximide and cholera toxin has been examined in rabbits. Pretreatment of rabbits with cycloheximide (20mg/kg, i.v.) reduced by 60% the secretory response to cholera enterotoxin in isolated ileal loops with intact blood supply. That this antisecretory effect of cycloheximide persists *in vitro* was evidenced by sodium and chloride flux measurements on mucosa isolated from these and control loops. Measurements of radioactive leucine incorporation into mucosal protein indicated that the dose of cycloheximide employed inhibited protein synthesis by 90%. This effect was independent of any effect of cycloheximide on amino acid uptake across the brush border. Adenyl cyclase activity and cyclic AMP levels in ileal mucosa of cycloheximide-pretreated and control animals indicated that cycloheximide did not diminish the cholera enterotoxin-induced increases in these parameters. Thus, cycloheximide reduces cholera enterotoxin-induced intestinal fluid production without interfering with the cholera enterotoxin-induced increase in adenyl cyclase acitvity or the consequent rise in cyclic AMP concentration. As this antisecretory effect persists *in vitro* a direct interaction of the antibiotic with mucosal cell ion transport mechanisms is probably involved, rather than an indirect effect mediated by other humoral or neurogenic factors. It is also suggested that the secretory response of the intestine to cholera enterotoxin does not involve either the synthesis of new adenyl cyclase or a protein modifying its activity.

GENERAL

Parasitology

0772 DIETARY FACTORS AFFECTING THE PATHOGENICITY OF ENTAMOEBA HISTOLYTICA IN RATS. *(E.)* Ross, G. W.; Knight, R. (London Sch. Hyg. Trop. Med., England). *Trans. Roy. Soc. Trop. Med. Hyg.* 67(4):560-567, 1973.

Weanling Wistar albino rats given protein-deficient diets for 2-4 weeks and then infected intracecally with *Entamoeba histolytica* trophozoites were more susceptible to infection compared with controls. The proportion of infected animals developing cecal ulceration also increased. Supplementation of the low protein diet with extra carbohydrate produced an even greater infection rate but the likelihood of cecal ulceration was lower. No relation between amebic infection and the bacterial flora or pH of the cecum was noted. However, the redox potential was lower in animals developing ulceration. The mechanism by which diet affects the outcome of amebi challenge is not clear, but these results show that diet alone can affect cecal histology and the redox potential of the cecal contents. This rat model may show that dietary factors are of importance in human amebiasis.

0773 STUDIES OF HUMAN AMEBIASIS. I. CLINICAL AND LABORATORY FINDINGS IN EIGHT CASES OF ACUTE AMEBIC COLITIS. *(E.)* Pittman, F. E.; El-Hashimi, W. K.; Pittman, J. C. (Med. Univ. South Carolina, Charleston). *Gastroenterology* 65(4):581-587, 1973.

In 8 patients presenting with bloody diarrhea amebi asis was diagnosed promptly and accurately by sig-

moidoscopy without bowel preparation or interfering
substances and by examining fresh exudate obtained
at time of sigmoidoscopy for motile hematophagous
trophozoites of *Entamoeba histolytica*. These 8 pa-
tients, aged 18-50 yr, lived within 60 miles of Char-
lestown, South Carolina, and only 1 had recently
traveled outside the state. Six of the 8 patients
lived in rural areas where there were shallow wells
and privies for disposal of sewage; the remaining 2
patients lived in the center of the city and denied
drinking well water. Amebae were seen in only 5 of 12
pretreatment colonic mucosal biopsies. Diffuse in-
flammation, compatible with mucosal abnormalities seen
in ulcerative or granulomatous colitis, was present
in all biopsies, and was the only histopathological
abnormality in 7. Amebic serology (indirect hemagglu-
tination) was positive in all patients and prompted
a search for amebae in 2 patients who had been
erroneously diagnosed as having granulomatous colitis.
All patients treated with metronidazole experienced
clinical cures, but parasitological failure did oc-
cur. Appropriate studies to establish or exclude the
iagnosis of amebiasis should be carried out in all
patients who present with a clinical and sigmoidoscop-
c picture of colitis. Clinical and parasitological
ollow-up is recommended for patients treated with
etronidazole for amebiasis.

774 NONDYSENTERIC INTESTINAL AMEBIASIS. TREATMENT WITH DILOXANIDE FUROATE. *(E.)* Wolfe,
. S. (Office Med. Services, Dept. State, Washington,
.C.) *J.A.M.A.* 224(12):1601-1604, 1973.

10-day course of diloxanide furoate therapy (500 mg
times a day for adults and 20 mg/kg/day in 3 divi-
ed doses for children) was administered and a complete
llow-up was made on 77 of 100 individuals with
tamoeba histolytica cysts or trophozoites in at least
e stool and the absence of severe symptoms or proctos-
pic findings compatible with acute amebic dysentery.
mptoms were present in 65 patients and 12 were
ymptomatic. Parasitological and symptomatic cures
re obtained in 65 of these 77 patients, including
l 12 patients with no symptoms, for a cure rate of
%. Of the 13 patients who were not cured, complete
mptomatic improvement occurred in 5, while at least
e pretreatment symptom persisted in the remaining 8.
second course of diloxanide furoate, given to
patients with persistent amebiasis, cured 3. Ad-
nistration of diloxanide furoate also cured con-
mitant *Entamoeba hartmannii* infections in 24 of the
infected patients. Side effects of diloxanide
roate consisted of excessive flatulence (78 patients),
sea (5), anorexia (3), diarrhea (2), and mild ab-
inal cramps (2), but all patients completed the
rse of treatment without incident. Blood counts
urine analysis showed no evidence of drug-induced
anges.

GENERAL

Regional Enteritis

0795 ABSCESS AND FISTULAE IN CROHN'S DISEASE. *(E.)* Steinberg, D. M.; Cooke, W. T.; Alexander-Williams, J. (Gen. Hosp., Birmingham, England). *Gut* 14(1):865-869, 1973.

In a series of 360 patients with Crohn's disease, 65 (18%) developed an abscess and/or fistula. Of a total of 59 abscesses, 13 occurred spontaneously and the remainder in patients who had undergone a previous operation. Of 60 fistulas, 13 developed in patients who had not undergone a laparotomy; 22 occurred after resection, 8 after a bypass procedur 4 after diagnostic laparotomy, and 13 after appendectomy. Simple drainage of 33 superficial abscess was followed by a persistent fistula in 28 cases. En bloc excision of 15 deep abscesses was associate with only 1 subsequent fistula and 1 recurrent abscess. Thus, conservative surgery (simple primary closure, proximal ileostomy, bypass, and colostomy) for fistula failed in 26 of 27 operations. Excision in continuity with the diseased segment of the intestine was successful in 42 of 50 operations

These results for radical surgery compare favorably with those reported for azathioprine therapy.

0796 CIRCULATING CARCINOEMBRYONIC ANTIGEN (CEA): RELATIONSHIP TO CLINICAL STATUS OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE.

(E.) Rule, A. H.; Goleski-Reilly, C.; Sachar, D. B.; Vandevoorde, J.; Janowitz, H. D. (Mount Sinai Sch. Med., New York, N.Y.). *Gut* 14(11):880-884, 1973.

Plasma levels of circulating carcinoembryonic antigen (CEA) were measured by zirconyl phosphate gel radioimmunoassay in 112 patients with chronic inflammatory bowel disease. The levels were then related to category, extent, duration, and severity of disease, as well as to the ages and surgical status of the patients. The distribution of CEA levels and their mean values were significantly raised over the levels in 33 normal control subjects, and were similar among patients with ulcerative colitis compared with those with granulomatous bowel disease. Positive values were defined as those in excess of 2.5 ng/ml. Positive assays occurred in 42% of ulcerative colitis patients, in 38% of Crohn's disease patients, and in 40% of the total group with inflammatory bowel disease. Among normal control subjects, only 3% were positive. Among inflammatory bowel disease patients, positive CEA assays occurred more frequently with more severe disease, more extensive anatomical involvement, younger ages, and shorter duration of disease. Those patients who had undergone total colectomy showed levels of circulating CEA and frequency of CEA positivity similar to those of an age-matched normal control group. CEA levels did not correspond with known cancer risk factors in patients with inflammatory bowel disease. Although rising or persisting plasma CEA values unrelated to severity and extent of disease may indicate an unfavourable prognosis in cancer, a single CEA value in patients with chronic inflammatory bowel disease is not a reliable indicator of cancer risk.

0797 EARLY COMPLICATIONS AFTER SURGICAL TREATMENT OF CROHN'S DISEASE.

(E.) Christiannsen, L.; Fischerman, K.; Nielsen, M. L. (Rigshosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 8(7):651-656, 1973.

Complications occurring in the first 10 weeks after surgery for Crohn's disease are analyzed in 68 patients (40 women and 28 men). Of the operations, 35 were primary and 33 were reoperations after primary operation in other hospitals. The most frequent complications were wound infections (31%), fistulas (29%), intra-abdominal abscesses (21%), and lung infiltrations appearing on x-ray (25%). Operative mortality was 4.4%. Postoperative intra-abdominal abscesses occurred significantly more often in patients who had a fistula or abscess before surgery. Other postoperative complications were not significantly more frequent in patients with preoperative complications. None of the complications was significantly correlated to type of operative procedure, number of operations, localization of Crohn's disease in the intestine, or preoperative treatment with corticosteroids.

0798 THE SUCCESSFUL CONSERVATIVE MANAGEMENT OF HIGH-OUTPUT ENTERO-CUTANEOUS FISTULAE.

(E.) Cocks, J.; Jones, R.; Kernutt, R.; O'Donovan, J. (Box Hill District Hosp., Melbourne, Australia). *Aust. N.Z. J. Surg.* 43(2):140-143, 1973.

Spontaneous closure of high output (1 liter/day) enterocutaneous fistulas arising in the small intestine occurred over 3-4 months in 3 patients treated by i.v. hyperalimentation. In 2 patients (men aged 32 and 69 yr), fistulas had persisted despite efforts to close leaking anastomoses surgically. The third patient (a 60-yr-old woman) would have required a difficult pancreatico-duodenectomy in the presence of sepsis; thus a conservative approach was used from the onset. The i.v. hyperalimentation involved giving more than 4000 calories/day in the form of fat, amino acids, and carbohydrates, with adequate vitamin, electrolyte, and trace element supplements. All patients recovered from long-term i.v. therapy complications that included sepsis, axillary vein thrombosis, and profuse facial flushing and fever. Other complications associated with subclavian catheters, such as pneumothorax and "lost" catheters, did not occur in these 3 cases.

0799 SERUM CARCINOEMBRYONIC ANTIGEN (CEA) IN PATIENTS WITH CHRONIC INFLAMMATORY BOWEL DISEASE.

(E.) Turner, M. D.; Kleinman, M. S.; Thayer, W. (Strong Mem. Hosp., Rochester, N.Y.). *Digestion* 9(2):116-123, 1973.

Serum carcinoembryonic antigen (CEA) in 78 patients with chronic inflammatory bowel disease was measured by a radioimmunoassay system. One of 17 patients with ulcerative proctitis, 3 of 30 with ulcerative colitis, and 4 of 31 with Crohn's disease had elevated serum CEA levels (3.5 to greater than 20 ng/ml). All patients with increased levels of CEA had symptomatic disease, but differences between serum CEA levels of symptomatic and asymptomatic patients were not statistically significant. Radiologic and other investigations showed no evidence of carcinoma of the colon in any of the 78 patients. It is unlikely that a single measurement of serum CEA by presently available methods is of value as a screening procedure for early carcinoma in patients with chronic inflammatory bowel disease. The potential value of sequential measurements remains to be determined.

0800 RESULTS FROM SURGICAL TREATMENT OF 46 PATIENTS WITH CROHN'S ILEOCOLITIS.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism a Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal trac Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized complilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism, and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

NOTE

Due to circumstances beyond our control, Gastroenterology Abstracts and Citations, Volume 7, Number 4, April 1973 inadvertently was mailed to another mailing list. We have arranged for additional copies to be printed and mailed to the Gastroenterology Abstracts and Citations mailing list. This should occur in the very near future.

We regret this inconvenience to our readers, and this office will continue surveillance to make sure that this issue will be mailed out correctly as soon as possible.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

0809 FAILURE OF PHENOBARBITAL AND MARIJUANA TO STIMULATE THE SMOOTH ENDOPLASMIC RETICULUM IN THE HUMAN INTESTINAL ABSORPTIVE CELL. *(E.)* Tytgat, G. N.; Saunders, D. R.; Rubin, C. E. (Dept. Med., Univ. Amsterdam, Netherlands). *Eur. J. Clin. Invest.* 3(4):363-370, 1973.

Phenobarbital (5-7 mg/kg/day, p.o., for 3-5 consecutive days) was given to 7 healthy volunteers who had been on a metabolic diet for at least 10 days and continued on that diet for 10 more. Each of 3 additional volunteers smoked up to 4 marijuana cigarettes/day, i.e., about 10-15 mg Δ 9-tetrahydrocannabinol/day. Diet was maintained similarly in all volunteers. A total of 180 intestinal biopsies were taken. The results indicated that there is no constant unequivocal increase in the percentage of electron micrograph pictures with a high number of microsomal profiles during the period of phenobarbital administration or during marijuana smoking. No significant increase in the average percentage of smooth endoplasmic reticulum hits occurred during the phenobarbital administration. No constant increase or decrease in microsomal protein content was observed during and after administration of phenobarbital or during and after smoking marijuana. No significant variations in alkaline phosphatase activity or in serum cholesterol and triglyceride levels were observed during these experiments. Moreover, the lipoprotein electrophoretic pattern did not reveal substantial changes during the pharmacological experiments. These results contrast with the susceptibility of the hepatocyte to smooth endoplasmic reticulum induction by phenobarbital.

0810 A STEREOLOGICAL STUDY OF INTRAHEPATIC BILE DUCTS. I. METHOD AND APPLICATION TO NORMAL LIVERS. *(E.)* Jorgensen, M. (Inst. Path., Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand. (A)* 81(5):657-662, 1973.

Intrahepatic bile ducts in tissue from 10 autopsies were examined by the stereological method. The material comprised liver tissue from 5 newborn children and 5 adults, aged 22, 31, 49, 60, and 65 yr; none of these patients had evidence of liver or biliary disease. Tissue, fixed in formalin and embedded in paraffin, was cut in 5-10 μm thick sections, which were stained with hematoxylin and eosin. Profiles (100) of sectioned bile ducts were drawn on tracing paper by means of a Leitz device, so that all ducts in a randomly chosen path were drawn. Each profile was numbered and its largest and shortest diameter measured in mm. From these figures the axial ratio was calculated. There was no systematic difference in axial ratio distribution with respect to age in the adult group, and no difference between children and adults. The profiles show that throughout life bile ducts in normal liver have a shape approximating a circular cylinder. The course of the ducts is straight over long segments. Partial parallelism is not a marked feature. Mean duct diameter increases slightly from the newborn period to adult life. Stereology is applicable to the distinction between relatively unrelated duct forms and their appearance in histologic slides. The method is less suitable for determination of ductal shape.

0811 LIGHT, FLUORESCENCE AND ELECTRON MICROSCOPIC STUDIES OF LYMPHOID CELLS IN THE SMALL INTESTINAL EPITHELIUM OF MICE. *(E.)* Glaister, J. R. (Nuffield Unit Lab. Animal Path., Edinburgh Univ., Scotland). *Int. Arch. Allergy Appl. Immunol.* 45(6): 854-867, 1973.

The lymphoid cells in the epithelium covering the villi of the small intestinal epithelium of the C3H mouse were examined by light, fluorescence, and electron microscopy. The population has a heterogeneous morphology with small and medium-sized lymphocytes predominating. Large lymphocytes and various types of pyroninophils are less common. The fate of these cells is also diverse; a small proportion degenerates, some migrate back into the lamina propria, and the remainder are probably lost into the lumen of the intestine. The presence of blast cells, blast cell-lymphocyte interaction, and limited antibody production suggests that an active immunological reaction is taking place in the epithelium. Whether the large number of non-pyroninophils in the epithelium are also involved in this reaction, or whether they have a different immunological function is not known.

0812 DEMONSTRATION OF FIBROUS COMPONENTS IN HEPATIC INTERPHASE NUCLEI BY HIGH RESOLUTION SCANNING ELECTRON MICROSCOPY. *(E.)* Tanaka, K.; Iino, A. (Tottori Univ. Sch. Med., Yonago, Japan). *Exp. Cell Res.* 81(1973):40-46, 1973.

Fibrous components were observed in the interphase nuclei of rabbit liver cells fixed with $KMnO_4$, split by the frozen-resin cracking method, and examined by high-resolution scanning electron microscopy. A fiber 350-700 Å in diameter was formed of about 250 Å coiled fibrils which were themselves formed of 100-150 Å supercoiled subfibrils. The fibers in the interphase nuclei were quite irregular in their arrangement, coiling to form greater fibers and twisting about one another like rope. The fibrous components appear compatible with the so-called chromatin fiber observed by whole-mount electron microscopy.

0813 THE FINE STRUCTURAL LOCALIZATION OF ALKALINE PHOSPHATASE ACTIVITY OF INTESTINAL MICROVILLI IN THE DEVELOPING CHICK EMBRYO. *(E.)* Ono, K. (Iwate Med. Univ., Morioka, Japan). *Acta Anat.* 86(1):71-82, 1973.

Fine structures and the development of the alkaline phosphatase activity of intestinal microvilli in the chick embryo were investigated electron microscopically. A primitive surface projection of the microvilli first appears in the duodenal and the jejunal cell surface of the 8-day chick embryo. The microvillous projections of the ileal epithelium are barely seen before the 10-day incubation stage. With the advance of embryonal stages, these primitive microvilli become increasingly numerous, regular in size, and finally project in a perpendicular direction from the free surface of the epithelium. When a mixture of 1-naphthyl phosphate and hexazotized pararosanilin was perfused intraluminally into the small intestine of living embryos, alkaline phosphatase reaction products appeared on the membrane of primitive projections of the duodenal and jejunal epithelium in the 8-day chick embryo. In the ileal epithelium, there was also definite, although very weak, alkaline phosphatase activity by this stage of development. After 20 days of incubation, alkaline phosphatase activity increased rapidly on the microvilli of the ileum, so that little difference was recognizable in the enzyme activity between the duodenum, jejunum, and ileum at the stage just before hatching. In glutaraldehyde-fixed material, azo-dye deposits are first detected on duodenal microvilli of the 14-day embryo. After 20 days of incubation, intensities of the alkaline phosphatase activity, as revealed in the glutaraldehyde-fixed small intestine, were essentially comparable with those revealed by the intravital perfusion method.

0814 PARENCHYMAL CELLS FROM ADULT RAT LIVER IN NONPROLIFERATING MONOLAYER CULTURE. II. ULTRASTRUCTURAL STUDIES. *(E.)* Chapman, G. S.; Jones, A. L.; Meyer, U. A.; Bissell, D. M. (VA Hosp., San Francisco, Calif.). *J. Cell Biol.* 59(3):735-747, 1973.

Hepatic parenchymal cells from adult rats, established *in vitro* as a monolayer, were evaluated by electron microscopy. Within 24 hr after the initial seeding, the incubated cells were polygonal and in close apposition with 3 to 6 neighboring cells. The ultrastructure of the monolayer cells was examined at this time and after 3 and 10 days of incubation. With the exception of a few enlarged mitochondria, organelles in both the 1- and 3-day monolayer cells were indistinguishable quantitatively and morphologically from those in the intact liver. After 10 days of incubation, however, the rough-surfaced endoplasmic reticulum had become dilated and vesiculated. In all cells studied, portions of the rough endoplasmic reticulum were found in a close spatial relationship to mitochondria. The observed frequency of this association supports previous suggestions that the organelle complex may represent a functional unit necessary for new membrane formation. The Golgi complexes of 1- and 3-day cells contained very low density lipoprotein-sized particles, which suggests that the monolayer cells synthesize lipoproteins. These electron microscope observations demonstrate that adult hepatic parenchymal cells in monolayer retain for several days the subcellular structural elements characteristic of normally functioning hepatocytes.

0815 EFFECTS OF SINGLE-DOSE PARTIAL-BODY X-IRRADIATION ON CELL PROLIFERATION IN THE MOUSE SMALL INTESTINAL EPITHELIUM. *(E.)* Lesher, J.; Lesher, S. (Allegheny Gen. Hosp., Pittsburgh, Pa.). *Radiat. Res.* 57(1):148-157, 1974.

The effects of partial body, single-dose, x-irradiation on the cell kinetics of the mouse small intestine were studied in male 100-day-old C57Bl/6J mice. Irradiation of the intestinal region with exposure of 300, 600, or 900r and with the anterior part of the mouse shielded produced changes in the epithelial cells of the small intestine which were similar in character to that observed with whole-body irradiation but were less severe and recovery took place more rapidly. The recovery was related to an increase in the proliferative population and an acceleration of the cell cycle. The increased proliferative population persisted longer in the partially shielded animals. The quantitative differences between the effects produced by lower partial-body (x-irradiation) as opposed to whole-body gamma-irradiation must be a reflection of more effective repair and/or better recovery. The only significant difference between the mice exposed to abdominal irradiation and those given whole-body irradiation is that in mice exposed to radiation to the abdomen alone all the organs in the anterior half of the animal received no irradiation. Therefore, it appears that the effects of irradiation on one organ system may possibly be modified by some factor or factors emanating from an unirradiated organ system.

0816 INFLUENCE OF VAGOTOMY ON PARIETAL CELL KINETICS IN THE RAT GASTRIC MUCOSA. *(E.)* Ley, R.; Willems, G.; Vansteenkiste, Y. (St. Pierre Univ. Hosp., Brussels, Belgium). *Gastroenterology* 65(5):764-772, 1973.

Four successive i.p. injections of ^{3}H-thymidine were performed in male Sprague-Dawley rats submitted to vagotomy and pyloroplasty, to pyloroplasty alone, or to sham operation. From 3 to 5 animals of each group were killed at intervals after these injections and the rate of appearance of labeled parietal cells in the fundic mucosa was studied autoradiographically. The percentages of labeled parietal cells observed after the 19th and 30th day were significantly lower in the vagotomized animals than in the control animals. This indicates that in rats, the production of young parietal cells is decreased after vagotomy. In a control experiment, DNA synthesis and mitotic indices were compared in rats submitted to one or the other of the three surgical procedures by using single injections of ^{3}H-thymidine. A slight increase in both parameters was observed in the fundic mucosa of the vagotomized animals. Thus, no decrease in mitotic activity of the fundic progenitor cells could explain the retarded parietal cell production after vagotomy.

0817 AUTORADIOGRAPHIC STUDIES OF LYMPHOID CELLS IN THE SMALL INTESTINAL EPITHELIUM OF THE MOUSE. *(E.)* Glaister, J. R. (Nuffield Unit Lab. Animal Path. Edinburgh Univ., Scotland). *Int. Arch. Allergy Appl. Immunol.* 45(6):844-853, 1973.

The labeling index of the lymphoid cell population in the small intestinal epithelium of the C3H mouse was

determined at various time intervals after single or
multiple i.p. injections of tritiated thymidine.
The results show that the population is composed on
both short-lived and long-lived lymphoid cells. The
generation time of short-lived cells was estimated
at 10-14 hr. Although the long-lived lymphocytes
appear to have a generation time in the order of
months, the actual number of these cells present in
the epithelium declines fairly rapidly with a half-
life of approximately 7 days. The function of the
short-lived population is unknown. Since the short-
lived cells include both pyroninophils and small and
edium-sized lymphocytes, both humoral and cellular
mmune responses can be taking place in the epithelium,
he former being seen as pyroninophilic cells equi-
alent to those of the germinal centers and plasma
ell precursors, the latter manifesting themselves
s migrating newly formed small lymphoid cells into
he epithelium. There is a relatively small long-
ived lymphocyte population in the epithelium. The
ymphoid cell population in the intestinal epithelium
ay be a complex immunological system which monitors
nd responds to a variety of antigenic stimuli in
r near the epithelium, forming part of the in-
estinal defense mechanism.

818 EMBRYOGENESIS OF THE ENTERIC GANGLIA IN
NORMAL MICE AND IN MICE THAT DEVELOP CON-
ENITAL AGANGLIONIC MEGACOLON. *(E.)* Webster, W.
Dept. Anat., Univ. Virginia, Charlottesville).
. *Embryol. Exp. Morphol.* 30(3):573-585, 1973.

he development of the enteric plexus in normal mice
nd in mice who develop aganglionic megacolon due to
he recessive gene piebald-lethal was examined by
erial frozen sections stained for esterase activity.
ontrary to the classical concept, all the enteric
anglia are from a single, vagal, neural crest source.
he immature ganglion cells first enter the gut by
y of the newly formed vagal outgrowth at 10 days
estation. The neuroblasts then migrate down the
t in a cranio-caudal direction, being replaced by
re neuroblasts from the vagus. By 15 days 12 hr
e process is complete and ganglion cells are
esent throughout the gut. The process is continuous
d there is no evidence of a lumbosacral origin for
y of the intramural ganglia. In mice which develop
anglionic megacolon the process is basically the
me except that the neuroblasts migrate at a slower
te than normal. The result is that the migration
the neuroblasts and the elongation of the gut are
t of phase so the migrating neuroblasts cannot
ach the end of the gut despite the fact they migrate
7 days longer than normal.

19 MATURATION OF GOBLET CELLS OF THE
MOUSE SMALL INTESTINE AS SHOWN BY
E UPTAKE OF ^{35}S-SODIUM SULFATE. *(E.)*
rzel, J.; Almeida, M. L. P. (Fac. Odontolgia
Piracicaba, S. P., Brazil). *Anat. Rec.*
7(4):519-524, 1973.

maturation of goblet cells of the small in-
tine was studied in male adult Swiss mice.
mice fed *ad libitum* were given a single i.p. injection of ^{35}S-sodium sulfate and sacrificed 1, 3, and 6 hr later. Plastic-embedded 1μ thick sections from duodenum, jejunum and ileum were radioautographed and the uptake of the ^{35}S by goblet cells was analyzed. Goblet cells of the small intestine originate in crypts and migrate to villi tips where they are released into the intestinal lumen. Radioautographic reaction appeared over all goblet cells, whether in the crypts or in the villi, indicating continual synthesis of sulfomucins. Analysis of counts over goblet cells at different levels of crypts and villi revealed that the cells of duodenum and jejunum become more active in sulfomucin synthesis, when they reach the upper half of the villi. In the ileum, although a similar maturation may occur, the results were not statistically significant.

0820 THE DEVELOPMENT OF THE DUODENAL MUCOSA OF THE CHICK FOLLOWING EXPOSURE TO 700r OF IONIZING RADIATION. *(E.)* Verzosa, Jr., V. S. (Coll. Med., Northwestern Univ., Chicago, Ill.). *Acta Med. Philippina* 9(1):18-49, 1973.

0821 SIALOGRAPHIC APPEARANCES OF THE NORMAL PAROTID GLAND. *(E.)* Ericson, S. (Dept. Oral Roentgenol., Umea Univ., Sweden). *Acta Radiol. Diagn.* 14(5):593-612, 1973.

0822 FINE STRUCTURE OF THE DIFFERENTIATING ACINI IN SUBMANDIBULAR GLANDS OF ISOPROTERENOL-TREATED RATS. *(E.)* Bressler, R. S. (Mt. Sinai Sch. Med., New York, N.Y.). *Am. J. Anat.* 138(4):431-448, 1973.

0823 PREPARATION OF INTESTINE AND OTHER ELONGATED SPECIMENS FOR HISTOLOGIC AND IMMUNOFLUORESCENT STUDIES. *(E.)* Loria, R. M.; Kibrick, S.; El-Bermani, A.; Broitman, S. A. (Boston Univ. Sch. Med., Mass.). *Am. J. Clin. Pathol.* 60(3):424-427, 1973.

0824 HEMATOPOIETIC TISSUE IN THE FOETAL LIVER OF THE RAT AT THE END OF GESTATION. IV. REPERCUSSIONS OF ITS EVOLUTION ON THE RED CELL POPULATION OF THE FOETAL BLOOD. *(Fr.)* Nagel, J. (Lab. Animal Physiol., Fac. Sci., Reims, France). *Arch. Anat. Microsc. Morphol. Exp.* 61(3):301-312, 1972.

0844 INHIBITION OF ILEAL WATER ABSORPTION BY INTRALUMINAL FATTY ACIDS: INFLUENCE OF CHAIN LENGTH, HYDROXYLATION, AND CONJUGATION OF FATTY ACIDS. *(E.)* Ammon, H. V.; Phillips, S. F. (Med. Coll. Wisconsin, Wood). *J. Clin. Invest.* 53(1):205-210, 1974.

The influence of fatty acids on ileal absorption of water, electrolytes, glucose, and taurocholate was examined in Thiry-Vella fistulas in 5 mongrel dogs. Fatty acid absorption also was measured. Segments of terminal ileum were perfused at steady state with isotonic electrolyte solutions containing 11.2 mM glucose, 4.5 mM taurocholate, and 0.1-5.0 mM fatty acid. Three C_{18} fatty acids, oleic acid, 10(9)-hydroxy-stearic acid, and ricinoleic acid, completely inhibited water absorption at 5 mM. Sodium, chloride, and potassium absorptions were inhibited in parallel with absorption of water. At 1 mM, ricinoleic acid was significantly more potent than oleic acid; the effect of 1 mM 10(9)-hydroxy-stearic acid was intermediate. Dodecanoic and decanoic acids were as effective as C_{18} fatty acids at 5 mM but octanoic and hexanoic acids were ineffective. The polar group of C_{18} fatty acids was modified by conjugating oleic and ricinoleic acids with taurine. When these compounds and a substituted C_{10} fatty acid, *p-n*-decylbenzenesulfonate, were perfused, water absorption was also inhibited. Short-chain fatty acids (C_3 and C_4) and their hydroxylated derivatives were ineffective at 5 mM. When water absorption was inhibited, absorption of glucose and taurocholate was decreased. The phenomenon of inhibition of water and electrolyte absorption by fatty acids may be relevant to steatorrhea and diarrhea in man.

0845 THE INFLUENCE OF PROTEIN MALNUTRITION ON ILEAL PERMEABILITY TO MACROMOLECULES IN THE RAT. *(E.)* Worthington, B. S.; Boatman, E. S. (Sch. Public Hlth. Community Med., Univ. Washington, Seattle). *Am. J. Dig. Dis.* 19(1):43-55, 1974.

Ileal absorption of intact protein was assessed in groups of control and protein-deficient Sprague-Dawley rats during a 5-month period of dietary protein restriction. At monthly intervals following diet initiation, 3 animals from both the control and deficient groups were administered horseradish peroxidase via ligated ileal loops either 15, 45, or 90 min before loop excision and processing for light and electron microscopy. Morphological evaluations revealed no change in pinocytotic activity during the 5 months of progressive protein malnutrition. After 3 months, however, partial deterioration of mucosal structure was observed with apparent separation of apical intercellular junctions and movement of peroxidase molecules directly between cells. Thus, the ileal epithelium, unlike its jejunal counterpart, does not respond to protein deficiency by increased pinocytotic activity but shows signs of intercellular barrier deterioration. Loss of intestinal barrier function to macromolecules might provide an intercellular pathway by which toxic substances from the distal small intestine enter the mucosa. Such a phenomenon could explain the severity of diarrhea in children with protein malnutrition.

0846 ION TRANSPORT IN RABBIT ILEAL MUCOSA. IV. BICARBONATE SECRETION. *(E.)* Dietz, J.; Field, M. (Harvard Med. Sch., Boston, Mass.). *Am. J. Physiol.* 225(4):858-861, 1973.

Secretion of HCO_3 by isolated New Zealand male rabbit ileal mucosa was studied under control conditions in the presence of dibutyryl cyclic AMP and in the presence of epinephrine. Tissues were clamped in low-volume Ussing chamber systems and bathed with 25 mM HCO_3-Ringer gassed with 5% CO_2 in O_2. HCO_3 concentration changes were determined by acidification and back-titration and volume changes were determined by counting ^{3}H-insulin. Luminal alkalinzation and serosal acidification were observed under control conditions and in the presence of dibutyryl cyclic AMP, the change being similar for both. Epinephrine abolished this apparent HCO_3 secretion. In all three cases, serosal acidification was greater than luminal alkalinization. Lactate measurements suggested that this difference was due to preferential release of lactic acid on the serosal side. The magnitudes of the net HCO_3 fluxes were in the ranges of previously measured residual ion fluxes. The results suggest that 1) HCO_3 is actively secreted by the ileum; 2) dibitutyryl cyclic AMP does not significantly increase the rate of secretion; 3) epinephrine abolishes net HCO_3 secretion; and 4) the residual ion flux is due predominantly to net HCO_3 secretion.

0847 ELECTROLYTE TRANSPORT IN RABBIT ILEUM. *(E.)* Binder, H. J.; Powell, D. W.; Tai, Y. H.; Curran, P. F. (Yale Univ. Sch. Med., New Haven, Conn.). *Am. J. Physiol.* 225(4):776-780, 1973.

Na and Cl transport across rabbit ileum *in vitro* was studied using a variety of bathing solutions. In solutions containing Cl and/or HCO_3, short-circuit current (I_{sc}) was always greater than net Na flux, but in Cl-HCO_3-free solution (Cl and HCO_3 replaced by isethionate) net Na flux was greater than I_{sc}. Addition of HCO_3 to the bathing solutions in the presence or absence of Cl caused a decrease in net Na absorption with little change in I_{sc}, and addition of HCO_3 in the presence of Cl caused a decrease in net Cl secretion. Addition of Cl in the presence or absence of HCO_3 caused an increase in Isc but little change in net Na flux. There was no set flux of Cl in Na-free solution. These observations are consistent with the presence of two ion transport systems in the ileum, one mediating Na absorption and one mediating electrolyte secretion. The secretory system could involve either electrogenic anion transport or neutral transport of NaCl and/or $NaHCO_3$, but detailed examination of the results suggests that the latter may be somewhat more likely.

0848 COUNTERCURRENT MULTIPLICATION OF SODIUM IN INTESTINAL VILLI DURING ABSORPTION OF SODIUM CHLORIDE. *(E.)* Haljamae, H.; Jodal, M.; Lundgren, O. (Dept. Histol., Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 89(4):480-493, 1973.

Sodium and potassium concentrations in the villous tissue, expressed as μg Na or K/mg tissue protein, were determined *in vivo* in anesthetized cats along the villous length during the absorption of isotonic saline solutions. Sodium concentrations were 3-4 times higher at the tip than at the villous base. The addition of 30 mmol glucose to the incubation medium increased the sodium concentration along the villous length, while this gradient was drastically decreased by ischemia or intense vasodilatation as well as by intra-arterial infusion of ouabain. The intracellular sodium and potassium concentrations at the villous base were calculated at 21 to 125 mEq/liter, resp., during isotonic saline absorption. The extracellular sodium concentration at the villous tip was estimated at 300-900 mEq/liter, corresponding to an interstitial osmolarity of 600-1600 milliosmol/liter. It is proposed that a countercurrent multiplication of sodium occurs in the villi resulting in a high interstitial osmolarity at the villous tip. The countercurrent multiplication of sodium, occurring during the absorption of sodium chloride, is of major importance for the absorption of water, particularly when this occurs against a luminal to tissue osmotic gradient. Absorption of any solute that increases plasma osmolarity in the villous capillary network would likely cause a transfer of water from villous central artery to villous capillaries. This, in turn, would lead to a high sodium chloride concentration in the extracellular space of the villous tip, enhancing water absorption.

0849 ION TRANSPORT IN RABBIT ILEAL MUCOSA. III. EFFECTS OF CATECHOLAMINES. *(E.)* Field, M.; McColl, I. (Harvard Med. Sch., Boston, Mass.). *Am. J. Physiol.* 225(4):852-857, 1973.

Effects of epinephrine and norepinephrine on ion transport in isolated rabbit ileal mucosa were studied in HCO_3-containing (25 mM HCO_3, 5% CO_2) and HCO_3-free (no HCO_3 or CO_2) Ringer solutions. In HCO_3-Ringer, epinephrine and norepinephrine (0.05 mM) produced rapid and sustained decreases in short-circuit current of more than 100 microampere/cm^2. In HCO_3-free Ringer (present on both sides of the mucosa or only on the luminal side), the decreases in short-circuit current were much smaller. In both Ringer solutions, norepinephrine reversed the increase in short-circuit current produced by theophylline but not that produced by cyclic AMP or its dibutyryl analogue. These short-circuit current changes did not occur with isoproterenol, were unaffected by propranalol, and were partially reversed by phentolamine, suggesting that they are alpha-adrenergic in nature. Na and Cl flux measurements demonstrated the following effects of epinephrine and norepinephrine in HCO_3-Ringer: an increase in net mucosa- (M) to-serosa (S) Na flux due to an increase in M-to-S unidirectional flux; an increase in net M-to-S Cl flux due both to an increase in M-to-S and a decrease in S-to-M unidirectional fluxes; and disappearance of the residual ion flux. Most of the short-circuit current change was due to the last of these effects. These effects were not seen in HCO_3-free Ringer. It is concluded that stimulation of alpha-adrenergic receptors in the ileal mucosa enhances active absorption of Na and Cl and reduces short-circuit current, probably by inhibiting net HCO_3 secretion.

0850 INFLUENCE OF FLOW RATE ON THE KINETICS OF ABSORPTION OF GLUCOSE AND LYSINE IN CHILDREN. *(E.)* Rey, F.; Driller, F.; Schmitz, J.; Rey, J. (Hosp. Enfants Malades, Paris, France). *Gastroenterology* 66(1):79-85, 1974.

The influence of flow rate on the kinetics of glucose and lysine absorption was studied in 20 normal children, aged 7 months to 5 yr, by using a double lumen tube. Absorption values at 7.5 ml/min were approximately twice those at 3.6 ml/min. The glucose concentration gradient between the proximal and distal orifices was not reduced at the lowest concentrations (18, 36, and 72 mM glucose infused) when the flow rate was increased from 3.6 to 7.5 ml/min. At the highest concentrations (135 and 270), increased flow rate produced a significant reduction of the concentration gradient. the lysine concentration gradient was not significantly modified by altering flow rate. In these conditions, perfusion rate does not increase the surface of mucosa really perfused. This effect is related to modifications of the apparent affinity constants. It is proposed that the flow rate altered the thickness of the unstirred water layers lining the microvilli and, consequently, the substrate concentrations at the contact of the transport sites. Assuming this, these results could further suggest that molecular diffusion through these water layers may be rate-limiting in the overall process of absorption, even for hydrosoluble substrates such as glucose and amino acids.

0851 FOOD IRON ABSORPTION IN MAN: APPLICATIONS OF THE TWO-POOL EXTRINSIC TAG METHOD TO MEASURE HEME AND NONHEME IRON ABSORPTION FROM THE WHOLE DIET. *(E.)* Bjorn-Rasmussen, E.; Hallberg, L.; Isaksson, B.; Arvidsson, B. (Dept. Med. II, Univ. Goteborg, Sweden). *J. Clin. Invest.* 53(1):247-255, 1974.

A new radioisotope method to measure iron absorption from the whole diet was used to test the accuracy of the two-pool extrinsic tag method. The method is based on the concept that food iron is absorbed from 2 pools, the heme iron pool and the nonheme iron pool, which can be expecially labeled with two radioiron isotopes given as hemoglobin and as an iron salt. The meals were composed as averages of 6-week food intake in the present material of 32 young enlisted men. The mean total heme and nonheme iron absorption in the subjects was 1.01 mg. This figure agrees well with the mean daily losses expected for this group of subjects (1.0 mg). Therefore, there are no major systematic errors in the present method to measure the total iron absorption from a mixed diet. Comparison of the absorption of heme and nonheme iron from the meals indicated significant correlation between the absorption of the two kinds of iron. However, a much greater fraction of the heme iron was absorbed (37%) than the nonheme iron (5%). The absorption both from breakfast and lunch was found to give a good prediction of the total daily nonheme iron absorption. There was a significant increase in iron absorption when the level of iron fortification of the meals was increased from 16.4 to 25.5 mg.

0889 STUDIES IN GASTROINTESTINAL INTERACTIONS. IV. GASTRIC EMPTYING OF A COMPOSITE MEAL IN MAN. THE INFLUENCE OF GLUCOSE. *(E.)* Johansson, C. (Karolinska Hospital, Stockholm, Sweden). *Scand. J. Gastroenterol.* 8(6):533-539, 1973.

Gastric emptying of a fluid standard test meal made up of milk protein, fat, and lactose was investigated in 7 healthy subjects and the effect of the addition of 10% glucose to the meal was examined. Following the glucose-free meal the emptying of water, protein, and fat into the duodenum was constant after an early, short rapid phase. The pattern of emptying for lactose was exponential. After addition of glucose the emptying of the meal could be divided into two separate phases, an initial phase characterized by a constant transfer of sugar and comparatively small amounts of water, protein, and fat, and a second coinciding in rates and patterns with those of the glucose-free meals. The results suggest that several mechanisms operate to control the gastric emptying rate during the course of emptying a composite meal.

0890 ELECTRICAL DISCHARGE OF SINGLE ENTERIC NEURONS OF GUINEA PIG SMALL INTESTINE. *(E.)* Wood, J. D. (Univ. Kansas Med. Ctr. Kansas City, Mo.). *Am. J. Physiol.* 225(5):1107-1113, 1973.

Microelectrode studies of single-unit activity in the myenteric plexus of the guinea pig jejunum revealed 3 kinds of intrinsic neurons that could be distinguished on the basis of pattern of electrical discharge. Burst-type units spontaneously discharged bursts of spikes at periodic intervals, mechanosensitive neurons were induced by mechanical stimulation to fire at a faster rate, and single-spike units gave single spontaneous action potentials at variable intervals. Spike-interval histograms for burst units were bell shaped with positive values of coefficient of skewness. Coefficient of variation of interspike interval was directly related to mean spike interval. Serial analysis of interspike intervals showed progressive increase in spike interval between the onset and end of each burst. Some burst units displayed periodic conversions from a burst pattern to a pattern of continuous discharge. Multiunit records showed occurrence of interactions between mechanoreceptors and burst-type neurons. Spike-interval histograms of single-spike units were platykurtic with relatively large variance of interspike interval.

0891 DIFFERENCES BETWEEN THE ACTION OF MORPHINE AND CHOLINERGIC AGENTS ON THE ELECTRICAL ACTIVITY OF THE COLON IN UNANESTHETIZED CATS. *(Fr.)* Wienbeck, M.; Christensen, J.; Weisbrodt, N. W. (Med. Clin., Univ. Marburg/Lahn, Germany). *Biol. Gastroenterol. (Paris)* 6(3):243-250, 1973.

Strain gauges and needle electrodes were sutured to the serosa of the colon of 6 cats to study the motor and electrical activity of the colon. Recordings were made on unanesthetized animals for 2-5 months after surgery. The basal electrical activity consisted of slow waves, spike potentials, and oscillations: their frequency was 5-6 cycles/sec, up to 10 cycles/sec, and 30-40 cycles/sec, resp. Sometimes the fast electrical activity took on a cyclical pattern with activity recurring at intervals of about 1 min. Some of the effects of bethanechol chloride (0.2 mg/kg i.m.), methacholine chloride (0.1 mg/kg i.m.), and neostigmine methyl sulfate (0.2 mg/kg) resembled those of morphine (0.1 mg/kg of the base as the chloride or sulfate i.m.). Both cholinergic agents and morphine caused a marked stimulation of fast electrical activity and contractions and decreased the slow-wave frequency. However, the cholinergic agents mainly activated the spike potentials, while morphine produced oscillations which sometimes lasted for several minutes. In addition, the spike bursts which occurred after administration of cholinergic agents were propagated along the colon, while the oscillations following morphine injection occurred independently in one or another segment of the colon and were not accompanied by propulsive activity. It is concluded that electromyography of the colon *in vivo* makes it possible to distinguish between otherwise hidden pharmacological effects and to account for clinical results obtained by treatment with cholinergic agents.

0892 EFFECTS OF UNPROCESSED BRAN OR COLON FUNCTION IN NORMAL SUBJECTS AND IN DIVERTICULAR DISEASE. *(E.)* Findlay, J. M.; Smith, A. N.; Mitchell, W. D.; Anderson, A. J. B.; Eastwood, M. A. (Western Gen. Hosp., Edinburgh, Scotland). *Lancet* (7849):146-149, 1974.

The effects of adding 20 gr of unprocessed bran to a habitual diet were studied in 6 control subjects and 7 patients with uncomplicated diverticular disease of the colon. Polyethylene glycol 4000

(PEG) and chromium sesquioxide (Cr_2O_3) were used to mark the liquid and solid phases of the gastrointestinal content, respectively. Transit-time was reduced significantly in patients with diverticular disease. Stool weight increased by an average of 63 g in normal subjects, but did not increase significantly in patients with diverticular disease (only 17 g). There was no significant change in the freeze-dried weights as a percentage of total weight on bran. In normals, the concentration of Cr_2O_3 remained unchanged, but P.E.G. concentration decreased. In patients with diverticular disease, the concentration of both markers fell by about 30%. It is concluded that the increase in stool weight observed in bran-fed controls was associated with an increase of solid material and associated nonsolvent water, but not an increase in interstitial water. The motility studies in the patients indicate no significant change in basal activity, but the response to food was associated with a fall in motility index of some 30% after 1 month on bran. The response to prostigmine, which produces intense cholinergic stimulation of the colon, fell by 44%. There would thus appear to be a diminution in response to stimuli in patients with diverticular disease who are fed bran.

0893 EFFECTS OF BACTERIAL FLORA ON CECAL SIZE AND TRANSIT RATE OF INTESTINAL CONTENTS IN MICE.

(E.) Iwai, H.; Ishihara, Y.; Yamanaka, J.; Ito, T. (Central Inst. Exp. Animals, Tokyo, Japan). *Jap. J. Exp. Med.* 43(4):297-305, 1973.

Effects of different bacterial flora on the cecal size and transit rate of intestinal contents were examined in germfree, gnotobiotic, and conventional mice. The cecum of conventional infant mice increased in size before the establishment of a decreased level of Enterobacteriaceae, attaining a size similar to that of adult conventional mice. In most ex-germfree mice having a reduced Enterobacteriaceae level after exposure to a conventional environment, the cecal size became as small as that of conventional mice. This occurred also in a few cases having a high level of the organisms. The cecum of gnotobiotic mice associated with *Escherichia coli*, *Streptococci faecales*, Lactobacillus, and Bacteroides was not reduced in size. A larger number of *E. coli* was excreted in feces. In mice associated with the same species of organisms as above plus 12 or 13 strains of strict anaerobes, the cecum was reduced in size to a conventional level excreting a high level of *E. coli* in feces. The transit rate of intestinal contents was extremely low in germfree compared with conventional mice, but in the gnotobiotic mice with normal-sized cecum, the transit rate was as high as in conventional mice. A significant correlation between cecal size and transit rate of intestinal contents was shown, indicating that some physiologic functions in the digestive tract of mice are regulated by the presence of intestinal bacterial flora. It is suggested that the cecum is a site where close relations between some host physiologic functions and microflora can be realized. It is further assumed, since the suppression of increase in cecal size occurs after the establishment of normal intestinal flora, that changes in some physiologic functions in mice and rats during early life are regulated by bacterial flora.

0894 EFFECTS OF TRANSECTION ON SMALL INTESTINAL SLOW-WAVE PROPAGATION VELOCITY.

(E.) Diamant, N. E.; Wong, J.; Chen, L. (Inst. Med. Sci. Univ. Toronto, Canada). *Am. J. Physiol.* 225(6):1497-1500, 1973.

The effect of duodenal transection on in situ slow-wave propagation velocity and frequency along the upper small intestine was studied in 9 mongrel anesthetized dogs. Before transection, the usual frequency plateau was seen in the upper small bowel with a decrease in propagation velocity along its length. Below the transection, propagation velocity was increased at each recording site along the new plateau of lower frequency with a gradient of decreasing velocity maintained along the plateau. When the frequency below the cut was varied, propagation velocity at each location was related inversely to slow-wave frequency. The change in velocity per unit change in slow-wave frequency was greatest proximally and decreased as one proceeded distally. Between animals, differences in duodenal slow-wave propagation velocity also related inversely to frequency differences between animals. The increase in slow-wave propagation velocity may be one cause of rapid transit of intestinal contents following operations (e.g., peptic ulcer surgery) that involve transection of the upper intestine.

0895 EFFECTS OF EXTRINSIC DENERVATION ON THE FLUORESCENCE OF MONOAMINES IN THE SMALL INTESTINE OF THE CAT.

(E.) Ahlman, H.; Enerback, L.; Kewenter, J.; Storm, B. (Dept. Pathol., Univ. Linkoping, Sweden). *Acta Physiol. Scand.* 89(3):429-435, 1973.

The effects of section of the nerves supplying the small intestine on the fluorescence of monoamines in the cat were studied *in vivo* at different times after the operation in 12 cats. Before denervation, biopsies from the jejunum and ileum were studied by a fluorescence method in order to observe the adrenergic innervation and the presence of 5-hydroxytryptamine (5-HT). In addition to the adrenergic fibers terminating around the ganglion cells of the intestinal nervous plexuses, other adrenergic fibers were seen in close connection with the muscle fibers in both muscular layers. The only location of 5-HT seemed to be in the enterochromaffin cells of the mucosa. After nerve section the completeness of the denervation was established in an acute experiment by means of electrical stimulation of the vagal and splanchnic nerves while registering the motility of a jejunal and an ileal loop. Afterwards the small intestinal wall was studied with the same histochemical fluorescence method. No changes were found in the bowel habits or in the general state of nutrition of the animals. The intestinal adrenergic innervation completely disappeared after denervation. The adrenergic innervation does not seen to be necessary for adequate peristaltic activity in the small intestine. 5-HT did not disappear after denervation but was found unchanged in the enterochromaffin cells.

0896 VAGAL RELAXATION OF THE STOMACH INDUCED FROM THE GASTRIC ANTRUM. *(E.)*

Abrahamsson, H. (Dept. Physiol., Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 89(3):406-414, 1973.

The effect of mechanical stimulation of the gastric antrum on gastric (corpus-fundus) motility was studied in 18 anesthetized cats. Antral distension elicited a pronounced corpus-fundus relaxation which was not blocked by 0.5 to 1.0 mg/kg atropine, 3.0 to 4.2 mg/kg guanethidine or by cervical spinal cord transection but was abolished by blockade of the vagal nerves. The "threshold stimulus" for eliciting the reflex response was an antral distension pressure between 5 and 10 cm H_2O. Stepwise increases of antral distension produced correspondingly increased corpus-fundus relaxations. A steady antral distension could keep the corpus-fundus part relaxed for at least 10 min. I.a. infusion of acetylcholine to the antrum produced antral contractions followed by a marked corpus-fundus relaxation which persisted after guanethidine. Electric afferent stimulation of antral nerve branches elicited a gastric relaxation similar to the corpus-fundus response to antral distension. It is concluded that activation of slowly adapting tension receptors, located in the antral gastric wall and with vagal afferents, elicits gastric relaxation by a reflex activation of the vagal non-adrenergic relaxatory fibers to the stomach. These reflex mechanisms are suggested to be involved in the control of gastric reservoir function (receptive relaxation) and gastric emptying.

0897 COLONIC MOTILITY IN THE CAT. V. INFLUENCE OF TELENCEPHALIC STIMULATION AND THE PERIPHERAL PATHWAYS MEDIATING THE EFFECTS. *(E.)*

Rostad, H. (Inst. Neurophysiol., Univ. Oslo, Norway). *Acta Physiol. Scand.* 89(2):169-181, 1973.

The cerebral cortex and intracerebral structures were stimulated in 50 lightly anesthetized cats while colonic motility was recorded using extraluminal strain gage transducers. Excitatory colonic responses were produced from the anterior ectosylvian gyrus (the second somatic sensory-motor area) and from a small zone around the anterior end of the lateral sulcus. These effects were mediated through the vagal nerves. Colonic inhibition resulted from stimulation of 3 separate cortical zones, the anterior sigmoid, the orbital and the anterior cingulate tyri. These effects were mediated mainly through the lumbar colonic nerves. Stimulation of the amygdaloid nuclei produced excitatory colonic effects mediated through the lumbar colonic nerves. Inhibitory effects were not obtained from the mygdala. Weak colonic contractions resulted from timulation of the olfactory bulb and tract and ere conveyed through the parasympathetic vagal and elvic nerves.

0898 PHYSIOLOGIC SPECIALIZATION AT ESOPHAGOGASTRIC JUNCTION IN THREE SPECIES. *(E.)*

Christensen, J.; Conklin, J. L.; Freeman, B. W. (Univ. Hosp., Univ. Iowa, Iowa City). *Am. J. Physiol.* 225(6):1265-1270, 1973.

In 10 opossums, 5 cats, and 5 rhesus monkeys comparisons were made of length-resting tension relationships and responses to low-frequency electrical field stimulation among serial 2 mm-wide strips cut transversely from the esophagogastric junction and adjacent stomach and esophageal body. Three regions are distinguished on the basis of the nature of the response to field stimulation. Strips from the stomach contracted during stimulation; those from the esophageal body contracted briefly after the end of the stimulus; strips from the esophagogastric junction relaxed during stimulation. Transitional areas lay between the 3 regions showing these tetrodotoxin-sensitive responses. The length-resting tension slopes of strips from the esophagogastric junction were steeper than those of strips from the stomach and esophageal body. The strips which relaxed with field stimulation included those with the steepest slopes of the length-resting tension relationship. Slopes of length-resting tension were poorly correlated with muscle mass. In all 3 species, intrinsic specialization occurs at the esophagogastric junction in the nature of the innervation and in the mechanical properties of the inner muscle layer.

0899 EFFECT OF CORPORAL AND ANTRAL GASTROJEJUNOSTOMY ON CANINE GASTRIC EMPTYING OF SOLID SPHERES AND LIQUIDS. *(E.)*

Kelly, K. A.; Morley, K. D.; Wilbur, B. G. (Mayo Clin., Rochester, Minn.). *Br. J. Surg.* 60(11):880-884, 1973.

Gastric emptying of solids and liquids was measured in 12 dogs with and without corporal or antral gastrojejunostomy. Both types of stoma hastened the onset but did not alter the time from onset to complete emptying of 40 small plastic spheres. Corporal gastrojejunostomy slowed the emptying of 400 ml. of 154 mM NaCl but not of 500 mM glucose, whereas antral gastrojejunostomy slowed the emptying of both. In spite of the presence of a stoma with a diameter about 4 times that of the spheres, the net rate of emptying of spheres from the stomach did not differ from that of the controls. Gastric emptying of liquids is slower after gastroenterostomy because of the circular movement of gastric content from the stomach to the duodenum and jejunum and back into the stomach again via the stoma. The slow emptying is a net result of 2 opposing fluxes: the discharge of gastric content through the pylorus and through the stomach, and the reentry of this content into the stomach via the stoma. The experiments indicate that gastro-enterostomy may aid the healing of duodenal ulcers by slowing the net rate of emptying of corrosive gastric juices and allowing small intestinal content to enter the stomach where it can buffer and neutralize hydrogen ions.

0900 EFFECT OF VAGOTOMY ON GALLBLADDER SIZE AND CONTRACTILITY IN THE DOG. *(E.)*

Amberg, J. R.; Jones, R. S.; Moss, A.; Gourlay, S.; Goldberg, H. I. (Vanderbilt Univ. Sch. Med., Nashville, Tenn.). *Invest. Radiol.* 8(6):371-376, 1973.

Planimetry of the radiographic image of the gallbladder was used to study the response of the gallbladder to cholecystokinin (CCK) in dogs. The resting size of the gallbladder in each dog was variable during the 6 observations made. Despite the resting size difference, good dose response curves were obtained using 1/4, 1/2, 1, 2, and 4 units of CCK/kg. The relative reduction of gallbladder size from the resting state was considered the response. After truncal vagotomy, there was an increase in the mean resting size of each gallbladder which ranged from 22% to 87%. Progressive increase in gallbladder size did not occur when measurements at 3 weeks post-vagotomy were compared with those made at 7 months. After truncal vagotomy, the response to CCK was not altered. Endogenous CCK release secondary to exogenous CCK stimulation of gastric acid secretion was also studied and found not to be a significant factor in gallbladder contraction. It was thus felt that the secondary effect of gastric achlorhydria produced by truncal vagotomy did not invalidate the CCK dose response data.

0901 THE RELATIONSHIP BETWEEN INHIBITION OF ACETYLCHOLINESTERASE AND SENSITIVITY OF THE RAT ILEUM TO CARBACHOL. *(E.)*

Foley, D. J.; Stitzel, R. E.; McPhillips, J. J. (West Virginia Univ. Med. Ctr., Morgantown). *Pharmacology* 10(5):298-305, 1973.

Repeated injections of the cholinesterase inhibitor disulfoton to female albino rats cause diminished sensitivity of the ileum to the spasmogenic action of carbachol. A slight degree of diminished sensitivity appeared after the second injection and diminished sensitivity increased as treatment progressed. Measurement of acetylcholinesterase activity of the ileum revealed that inhibition of the enzyme also became greater as treatment progressed. When the injections of disulfoton were discontinued acetylcholinesterase levels returned to normal sometime between 2 and 5 days after the last injection of disulfoton whereas normal sensitivity to carbachol was not restored until sometime between 5 and 8 days. Repeated injections of echothiophate, parathion and OMPA also produced diminished sensitivity to the spasmogenic action of carbachol.

0902 CRYSTALLINE PANCREATIC GLUCAGON--A NEW SPASMOLYTIC AGENT: RESULTS OF COMPARATIVE ENDOSCOPIC AND ELECTROMANOMETRIC INVESTIGATIONS IN THE PROXIMAL GASTROINTESTINAL TRACT. *(E.)*

Paul, F.; Misaki, F.; Seifert, E. (Med. Sch., Hannover, Germany). *Endoscopy* 5(4):199-204, 1973.

Inhibition of peristalsis and reduction of muscle tone is desirable or necessary for the majority of diagnostic and therapeutic endoscopic procedures on the proximal gastrointestinal tract. Spasmolytics with atropine-like activity, or beta-receptor blockers are not free from undesirable side-effects at pharmacological doses. The ability of crystalline pancreatic glucagon as a single i.v. injection or as an i.v. infusion over a 30-min period to suppress motor activity in the stomach and duodenum of 30 patients was demonstrated both endoscopically and manometrically. The inhibitory effect begins within less than 1 minute, and persists for about 15 min. After this the motor activity returns gradually and increasingly. The period of motor quiescence is usually sufficient for careful endoscopic examination or for endoscopic operative procedures. No subjective side-effects were observed at the 0.2 mg dose in any case. Crystalline glucagon, therefore, appears to be the most suitable agent currently available for the reduction of tone and inhibition of peristalsis in the proximal gastrointestinal tract. The field of use of this potent "physiological spasmolytic" certainly extends beyond gastrointestinal endoscopy.

0903 PRESSURE RESPONSES TO CHOLINERGIC AND ADRENERGIC AGENTS IN THE FUNDUS, CORPUS, AND ANTRUM OF ISOLATED RAT AND GUINEA-PIG STOMACHS. *(E.)*

Haffner, J. F. W. (Dept. Pharmacol., Univ. Oslo, Norway). *Acta Chir. Scand.* 139(7):650-655, 1973.

The effects of acetylcholine, carbachol, adrenalin, noradrenalin, phenylephrine and isoprenaline on the pressure in the fundus, corpus and antrum of 7 male albino Wistar rats and 6 male guinea-pig stomachs, were studied *in vitro*, and compared with those previously obtained in rabbit stomachs. As found previously the pressure changes in the antrum were brief and rhythmic (4-7/min) while those in the fundus were slow and of many minutes' duration. The corpus appeared to represent a transitional zone. These motility patterns are characteristic of mammalian stomachs in general. The cholinergic agents caused a sustained pressure-increase in the fundus, and augmented amplitude and rate of contractions in the antrum. Adrenergic β-receptor stimulation with isoprenaline gave a sustained loss of pressure in the corpus and fundus and prolonged reduction of the rhythmic contractions in the antrum. α-Receptor stimulation with phenylephrine also inhibited contractions in the antrum, but the response in the corpus and fundus was biphasic; a brief relaxation preceding a sustained increase in pressure. Contrary to the rabbit preparations this secondary increase rarely exceeded the initial pressure, probably due to relatively high spontaneously developed pressure in rat and guinea-pig stomachs. The effects of adrenalin and noradrenalin were mixtures of α- and β-receptor responses, but generally they were more like the effects of phenylephrine than those of isoprenaline.

0904 IS THE PRIMARY PERISTALTIC CONTRACTION OF THE CANINE ESOPHAGUS BOLUS DEPENDENT? *(E.)*

Janssens, J.; Valembois, P.; Vantrappen, G.; Hellemann, J.; Pelemans, W. (Lab. Gastroenterol.

Physiopathol., Louvain, Belgium). *Gastroenterology* 65(5):750-756, 1973.

The necessity of a bolus for the progression of the primary esophageal peristaltic contraction was examined in 20 mongrel dogs. Esophageal transection with bolus deviation was carried out both at the cervical and at the thoracic level, with the vagal innervation remaining intact. If the swallowed bolus was deviated at the cervical level no peristaltic contraction occurred in the thoracic esophagus, whereas a normal peristaltic progression was possible if the bolus was deviated at the thoracic level. Consequently, a primary peristaltic contraction is entirely bolus-dependent only in its course through the cervical esophagus but not through the thoracic part of the gullet. Two mechanisms seem to be involved in the production of a peristaltic esophageal contraction: the central regulating mechanism in the medulla oblongata, and afferent information originating in the esophagus by the presence of a bolus. The latter is a prerequisite at the cervical level but not at the thoracic level. In the thoracic part of the gullet, however, it greatly facilitates the peristaltic progression of the esophageal contraction.

0905 ELECTRICAL AND CONTRACTILE ACTIVITIES OF THE SMALL INTESTINE OF THE CAT. *(E.)* Weisbrodt, N. W. (Univ. of Texas Med. Sch., Houston). *Am. J. Dig. Dis.* 19(2):93-99, 1974.

Five conscious cats were studied in the fasted and fed states to characterize the electrical and contractile activities of the feline small intestine. Slow waves were present at a frequency which decreased from 18 cycles/min in the duodenum to 13 cycles/min in the terminal ileum. There was a frequency "plateau" over the proximal 40 to 60% of intestine where the slow waves were coupled. Spike potentials of 2 types were present. The majority of spikes occurred only during the depolarization phase of the slow waves and were accompanied by phasic contractions. The second type of spiking (occurring only in fasted animals) was characterized by a 4- to 16-sec prolonged burst of spike potentials that first appeared in the upper small bowel and spread aborally. This burst was accompanied by a large tonic contraction. The slow waves were disrupted by the prolonged burst. These experiments demonstrate that the small intestine of the cat exhibits many of the same electrical and mechanical activities present in both dog and man. The prolonged bursts are not entirely analogous, however, as their periodicity is not as regular as the canine migrating myoelectric complex, and the contraction associated with the prolonged burst consists of a single, fused, tonic contraction which lasts for several seconds rather than a series of large-amplitude, phasic contractions.

0906 MIGRATING SPIKE BURSTS AND ELECTRICAL SLOW WAVES IN THE CAT COLON: EFFECT OF SECTIONING. *(E.)* Christensen, J.; Anuras, S.; Hauser, R. L. (Univ. Hosp., Iowa City). *Gastroenterology* 66(2):240-247, 1974.

The circular muscle electromyogram was recorded with up to 16 electrodes spaced uniformly along the whole cat colon *in vitro* before and after complete division of the colon between the electrodes. Before division, the electromyogram of the proximal colon contained slow waves with superimposed short spike bursts, while the distal three-fourths of the colon exhibited both slow waves and a periodic prolonged migrating spike burst. Seventy percent of migrating spike bursts started about the hepatic flexure of the colon and spread aborad: 30% started distally and spread orad. The period of the bursts was 74.3 to 83.0 sec, their duration 26.6 to 35.8 sec, and their velocity, 5.15 mm/sec aborad and 4.77 mm/sec orad. The migrating spike bursts were abolished by sectioning of the colon. Before partition, slow wave frequency was 4.5 cycles/min in the most proximal 10% of the colon, and 6.0 cycles/min in the most distal 10%, with intermediate values at intermediate points. After partition, slow wave frequency declined to an average of 1.9 cycles/min, 44% of the control value, in the most proximal 10% of the colon, and rose to an average of 7.3 cycles/min, 121% of the control value, in the most distal 10%. The migrating spike bursts and the slow waves appear to be unrelated. It is not possible to be certain of the influence of the polarity of the electromyographic events upon movements of the wall or on the direction of the fecal flow, for experiments correlating fecal flow, wall movements and electromyography have yet to be done. Nevertheless, the polarity of these electrical signals, if they are analogous to the similar signals in the stomach and small bowel may be expected to influence patterns of flow in the colon by affecting patterns of wall movement.

0907 EFFECTS OF A TEST OF PSYCHO-VISCERAL REACTIVITY ON GASTROINTESTINAL MOTILITY. *(Fr.)* Labo, G.; Lanfranchi, G. A.; Barbara, L.; Trombini, G.; Bortolotti, M.; Miglioli, M. (Inst. Med. Path., Univ. Bologna, Italy). *Arch. Fr. Mal. App. Dig.* 62(6):473-480, 1973.

SECRETION AND METABOLISM

0915 SYSTEMIC IMMUNITY AFTER LOCAL ANTIGENIC STIMULATION OF THE LYMPHOID TISSUE OF THE GASTROINTESTINAL TRACT. *(E.)* Rothberg, R. M.; Kraft, S. C.; Michalek, S. M. (Dept. Pediatr., Univ. Chicago, Ill.). *J. Immunol.* 111(6):1906-1913, 1973.

The distribution of antibody-producing cells (APC) in lymphoid tissues of New Zealand white rats immunized p.o. with bovine serum albumin (BSA, 0.1% in drinking water/day) was compared with that in animals immunized i.v. (50 mg) or s.c. (7 mg) by determining the concentration of direct and indirect plaque-forming cells in the lymphoid tissues. The spleen was the major site of APC in the i.v. immunized animals and APC predominated in the peripheral lymph nodes of the s.c. immunized group. In contrast, a major site of APC in the orally immunized animals was not directly identified. The concentrations of APC in the spleens of the orally immunized animals were similar to those in the s.c. immunized group, and a relative absence of APC was found in the peripheral and mesenteric lymph nodes, appendix, and Peyer's patches from orally immunized animals. Rabbits ingesting the antigen for several weeks were given 50 mg BSA i.v. and the concentrations of APC in the systemic lymphoid tissues were determined 3 days later. Plaque-forming cells were not detectable 3 days after an i.v. injection of BSA given to previously nonimmunized animals, although at this time a marked increase in their concentration was detected in the lymphoid tissues of the i.v. challenged-orally immunized animals. These findings provide additional evidence that the major site of both secretory and circulating antibody production after local antigenic stimulation at gastrointestinal mucosal surfaces is gut-associated lymphoid tissues and that systemic lymphoid tissues acquire the ability to produce anti-BSA.

0916 METABOLISM OF ^{125}I-LABELED SYNTHETIC HUMAN GASTRIN IN THE DOG AFTER PORTAL INJECTION. *(Fr.)* Bali, J. P.; Balmes, J. L.; Sellami, A.; Fournajoux, J.; Cayrol, B.; Khazrai, H. (St. Eloi Hosp., Montpellier, France). *Biol. Gastroenterol. (Paris)* 6(2):119-127, 1973.

After injection of 100 ng of ^{125}I-labeled gastrin into the portal vein, plasma clearance of gastrin, the radioactivity of various organs and secretions (urine, bile, gastric juice), and the immunoreactivity of the gastrin were studied in dogs. The plasma clearance curves were biexponential. The concentration of radioactivity in the peripheral veins may be considered to be that of the peripheral compartment, while the intestinal viscera should be considered to represent the central compartment since exchange there is very rapid. These curves show a rapid tissue distribution with a slower degradation. Equilibrium between the 2 compartments was reached after 12 min. No significant differences were found in organ radioactivities, indicating that gastrin is not preferentially metabolized at any one site. Radioactivity was low in the secretions studied confirming the interpretation of the plasma clearance curves. A study of gastrin degradation, measured by the loss in its ability to become adsorbed to carbon and its loss in immunoreactivity, confirmed that the hormone was degraded in 12 min. Its immunoreactivity decreased 50% when it passed through the hepatic parenchyma. The higher levels of immunoreactivity in peripheral veins than in peripheral arteries can be interpreted as preferential retention of the nonimmunoreactive degradation products of gastrin.

0934 A WORKING HYPOTHESIS FOR URECHOLINE EFFECTS ON HISTAMINE STIMULATION OF GASTRIC SECRETION. *(E.)* Hirschowitz, B. I.; Hutchison, G. A. (Dept. Med., Univ. Alabama, Birmingham). *Scand. J. Gastroenterol.* 8(8):569-576, 1973.

Gastric juice volume, H and Cl secreted during dose-response studies in 5 dogs with gastric fistula with histamine alone (2-125 μg/kg/hr, each dose given separately for 4 1/2 hr), with Bethanechol alone (10-80 μg/kg/hr), and with histamine (2-50 μg/kr/hr) given against a constant dose background of Bethanechol (40 μg/kg/hr) are described by kinetics conforming to Michaelis-Menten models. Bethanechol produced potentiation of the histamine dose response (increased Vmax) as well as synergism (multiplying the effect of histamine). For the dose of Bethanechol used here, Vmax for peak H$^+$ output was increased by 32% from 35 to 46.3 mEq/hr, while the effect of histamine was multiplied 3.0 times at all doses. Comparable effects were seen on water and Cl. This model may be used to explain the effects of Bethanechol, vagotomy, and anticholinergics on histamine dose response. The effect on pepsin secretion was only additive and thus different from those effects noted on electrolyte secretion.

0935 ADRENERGIC AND SEROTONINERGIC MECHANISMS IN GASTRIC SECRETION IN RATS. *(E.)* Fjalland, B. (Dept. Pharmacol. Toxicol., H. Lundbeck & Co., Copenhagen-Valby, Denmark). *Acta Pharmacol. Toxicol. (Kbh.)* 33(2):103-112, 1973.

The influence of adrenergic and serotoninergic mechanisms on gastric secretion was investigated using fistula- and pylorus-ligated male Wistar rats. Secretion was increased by the tyrosine hydroxylase inhibitor α-methyltyrosine (80 mg/kg s.c.). This effect was reversed by L-DOPA (200 mg/kg s.c.). 6-Hydroxydopamine (30 mg/kg i.v.) also increased gastric output. The tryptophane hydroxylase inhibitor *p*-chlorophenylalanine (100 mg/kg i.p. for 3 consecutive days) reduced gastric output and abolished the increase in gastric secretion induced by α-methyltyrosine. The antisecretory effect of serotonin (2 mg/kg s.c.) was antagonized by α-methyltyrosine. Pretreatment with 6-hydroxydopamine also diminished the antisecretory effect of serotonin. The possible existence of an inhibiting peripheral adrenergic tonus in the regulation of gastric secretion in rats is indicated. The antisecretory effect of large doses of serotonin may be due to displacement of noradrenaline in catecholamine neurones. The data also suggest the existence of a balance between serotoninergic and adrenergic mechanisms in the regulation of gastric secretion in rats.

0936 SECRETION AND ELECTRICAL ACTIVITY OF A UNILATERAL IN VITRO GASTRIC MUCOSA. *(E.)* Makhlouf, G. M.; Duckworth, G. R. (Med. Coll. Virginia, Richmond). *Gastroenterology* 65(6):907-911, 1973.

An *in vitro* unilateral preparation of gastric mucosa is described in which only the serosal side is bathed with a nutrient solution. The preparation permits direct measurement of secretory flow rate and ionic concentration and a continuous recording of transmucosal potential difference. Analysis of amphibian (leopard frog, *Rana pipiens*) secretion obtained in this manner disclosed striking similarities to the *in vivo* mammalian secretion. Thus, the concentrations of Na$^+$ and H$^+$ varied inversely, while the concentrations of K$^+$ and H$^+$ varied directly. Secretion became hypo-osmotic at intermediate acidities, but tended to osmotic equilibrium at high flow rates. Neither the early [K$^+$] transients nor the late decline in [K$^+$ concentrations] were observed *in vitro*. The transmucosal potential difference, after correction for junction potentials, did not alter with the development of secretion. With recent developments in the study of mammalian gastric secretion *in vitro*, this technique can now be adapted to the direct study of mammalian active and passive secretory mechanisms.

0937 EFFECT OF GASTRIC MUCOSAL ACIDIFICATION ON THE ACTION OF PEPSIGOGUES. *(E.)* Johnson, L. R. (Univ. Texas Med. Sch., Houston). *Am. J. Physiol.* 225(6):1411-1415, 1973.

Pepsin secretion was studied in 3 dogs with vagally denervated pouches of the oxyntic gland area. Experiments lasted 3 hr and consisted of 12 15-min collections of 50 ml of fluid which had been put in the pouch at the start of each period plus any secretions during that 15 min. After 1 hr of collections, either NaCl, histamine, pentagastrin, Bethanechol, or secretin was infused i.v. for the remainder of the experiment. Pepsin dose-response curves for each drug were constructed during irrigation of the pouches with phosphate buffer, pH 7.5 and 100 mN HCl. Irrigation of the pouches with 100 mN HCl resulted in a 3-fold stimulation of pepsin secretion. Pentagastrin (4.0-8.0 μg/kg/hr) produced no pepsin secretion in the presence of buffer and caused no increase over that stimulated by topical acid alone. Histamine (0.01-0.08 mg/kg/hr), Bethanechol (0.005-0.04 mg/kg/hr), and secretin (1.0-4.0 U/kg/hr) stimulated pepsin secretion in the presence of buffer, and acid significantly shifted these dose-response curves to the left. Acidification of the pouch significantly increased the maximal response to secretin and histamine, but not Bethanechol. Secretin was much more dependent on the presence of acid than was histamine or Bethanechol. The presence of acid in the stomach contributes significantly to the pepsigogic effects of Bethanechol, histamine, and secretin; pentagastrin does not stimulate pepsin secretion.

0959 EFFECT OF CERULEIN ON EXOCRINE PANCREATIC SECRETION IN THE RAT: KINETICS AND DOSE-RESPONSE RELATIONSHIP. *(Fr.)* Debray, C.; Vaille, C.; de La Tour, J.; Roze, C.; Souchard, M.; Chariot, J.; Fox, A. (Bichat Hosp., Paris, France). *Biol. Gastroenterol. (Paris)* 6(2):97-104, 1973.

Pancreatic secretion was studied in fasting anesthetized rats in response to a single rapid injection of cerulein (12-3,000 ng/kg i.v.) administered during continuous infusion of secretin (6 U/kg/hr i.v.). The output of pancreatic juice, total protein concentration and output, and amylase activity and output were measured. Maximal protein concentrations in the pancreatic juice were reached with cerulein doses of 330 ng/kg or higher, and maximal amylase activities were reached with doses of 110 ng/kg or higher. At larger doses the amylase activity remained constant but its output decreased due to inhibition of water secretion. Water secretion was stimulated only slightly by 110 and 330 ng/kg of cerulein and decreased with larger doses. This resulted in a complex log dose/response curve.

0960 PANCREAS ACINAR CELL DIFFERENTIATION: VIII. EFFECT OF METHIONINE ON DNA SYNTHESIS OF PANCREAS ANLAGE IN ORGAN CULTURE. *(E.)* Parsa, I.; Marsh, W. H.; Fitzgerald, P. J. (Downstate Med. Ctr., Brooklyn, N.Y.). *Exp. Cell Res.* 82(2):466-468, 1973.

Rat pancreas embryonic rudiments incubated in a control medium containing 80 mg/liter methionine grew and differentiated during 9 days of organ culture to adult acinar cells characterized by zymogen granules and relatively high levels of enzyme activity. Incubation of the anlagen in a medium with a lower methionine concentration (30 mg/liter) gave growth to a comparable size but no acinar cell formation, no zymogen granules, and no increases of enzyme activity. Anlagen incubated in the medium showed a marked decrease of the autoradiographic labeling index of acinar cell nuclei after exposure to ^{3}H-thymidine during the period of organ culture, whereas culture of anlagen in the medium with a lower methionine concentration led to far less decrease of the acinar cell labeling index. When anlagen which had been grown in the lower methionine concentration medium for 9 days were incubated for 3 additional days in the control medium there was a highly significant drop in the previously high labeling index. The higher level of methionine in the control medium may have been involved in the synthesis of, or the methylation of, an inhibitor of DNA synthesis.

0961 EFFECT OF BETHANECHOL CHLORIDE ON PROTEIN SYNTHESIS IN RAT PANCREAS. *(E.)* Webster, P. D.; Black, O.; Morisset, J. A. (VA Hosp., Augusta, Ga.). *Am. J. Dig. Dis.* 19(2):167-173, 1974.

The effect of bethanechol chloride on protein synthesis was studied in the pancreas of male albino Sprague-Dawley rats. Rats were given either saline or bethanechol chloride in doses of 0.1, 1.0, 2.0, 4.0, and 12.0 mg/kg body wt and killed after 10, 20, 40, 60, 90, 120, and 180 min, resp. Pancreatic protein synthesis was measured by determining *in vitro* incorporation of L-phenylalanine-^{14}C into whole tissue and microsomal protein fractions as well as purified amylase. Effects of bethanechol chloride on secretion were estimated by examining residual amylase content. Doses of 1.0 mg/kg resulted in 23% increases in incorporation of label into tissue proteins and 39% increases in incorporation into microsomal proteins at 20 min. A dose of 2.0 mg/kg resulted in 18 and 31% increases in incorporation into tissue proteins at 40 and 60 min as well as 34 and 14% increases in incorporation into microsomal proteins at 60 and 90 min. Doses of 4.0 mg/kg decreased incorporation into tissue proteins; that is, -36, -19, and -15% at 20, 40, and 60 min and -36, -22, and -14% decreases into microsomal proteins. A dose of 12 mg/kg was associated with -36, -38, and -28% decreases in incorporation into microsomal proteins at 60, 120, and 180 min. These studies show that small doses of bethanechol chloride were associated with induction of pancreatic protein synthesis and secretion. Large doses, on the other hand, were associated with decreased amino acid incorporation. These studies point out the importance of careful attention to dose and time of study.

0962 CHYMOTRYPSINOGEN IN THE INTESTINE OF RATS FED SOYBEAN TRYPSIN INHIBITOR AND ITS INABILITY TO SUPPRESS PANCREATIC ENZYME SECRETIONS. *(E.)* Lyman, R. L.; Olds, B. A.; Green, G. M. (Dept. Nutr. Sci., Univ. California, Berkeley). *J. Nutr.* 104(1):105-110, 1974.

The effect of soybean trypsin inhibitor (SBTI) on changes in the intestinal activities of pancreatic enzymes was studied to provide an explanation for the pancreatic enzyme response evoked when SBTI is fed to rats. Sprague-Dawley rats were intubated with either a control diet or diet containing SBTI. One hr after feeding, intestinal contents were removed and washed with either saline or saline containing chicken ovomucoid. Trypsin and amylase activities were determined and chymotrypsin activity was measured before and after incubation with trypsin. In control rats, intestinal chymotrypsin activity was not increased by incubation with trypsin. In animals fed SBTI, however, trypsin incubation increased intestinal chymotrypsin activity to 3 to 5 times the preincubation levels. Intestinal trypsin activity of rats fed SBTI was reduced to less than 10% of control values. Continuous infusion of purified bovine chymotrypsin or chymotrypsinogen into rats with a bile-pancreatic juice fistula demonstrated that while chymotrypsin suppressed pancreatic enzyme output, chymotrypsinogen did not. It was concluded, therefore, that SBTI acts to stimulate pancreatic secretion by binding intestinal trypsin so tightly it cannot fully activate chymotrypsinogen. Since chymotrypsinogen cannot suppress pancreatic secretion, SBTI effectively removes both enzymes from the intestine. An increased pancreatic enzyme secretion is initiated because of loss of the negative feedback regulation normally exerted by the active enzymes.

0963 EFFECT OF ACTINOMYCIN D, PANCREOZYMIN AND SECRETIN ON RNA SYNTHESIS AND PROTEIN SYNTHESIS AND PROTEIN SYNTHESIS MEASURED IN VIVO IN RAT PANCREAS. *(E.)* Reggio, H.; Cailla, H. L. (Ctr. Biochem. Mol. Biol., Marseille, France). *Biochim. Biophys. Acta* 338(1):37-42, 1974.

The effect of actinomycin D, pancreozymin and secretin on RNA synthesis and protein synthesis was measured *in vivo* in the pancreas of Wistar male rats. The maximum inhibition of RNA synthesis in the pancreas is obtained when the rats are treated with 2 mg/kg actinomycin. In the absence of any other drug, actinomycin inhibits (^{3}H)adenine incorporation into salt-insoluble RNA by 96.3%. When actinomycin is injected into pentobarbital-treated rats or into rats treated with pentobarbital and infused with secretin and pancreozymin, similar inhibition of RNA synthesis is observed. Treatment with pentobarbital alone induces a 70% decrease in (^{3}H)adenine incorporation. A similar decrease is observed even if rats are infused with pancreozymin and secretin in addition to pentobarbital. When (^{3}H)adenine is replaced by (^{32}P)orthophosphate as tracer, similar results are obtained with both pancreas and liver. (9) L-(^{14}C)valine incorporation into protein is lowered by about 50% when rats are treated for 4 hr with actinomycin. When rats are injected with pentobarbital alone, valine incorporation is reduced by 80%. Pancreozymin enhances protein synthesis and its effect is not modified by actinomycin. The level of amylase is lowered in the presence of hormones; the level is lowered to a lesser extent in the presence of actinomycin. Specific activity of free intrapancreatic valine was not modified either by actinomycin or by hormone treatment.

0964 EFFECT OF VARIOUS PROSTAGLANDINS AND SEROTONIN ON PROTEIN SECRETION FROM RAT EXOCRINE PANCREAS. *(E.)* Heisler, S. (Univ. Hosp. Ctr., Sherbrooke, Canada). *Experientia* 29(10):1234-1235, 1973.

To test whether prostaglandins E_2 and $F_{2\alpha}$ in any way regulate secretory events in female Wistar rat exocrine pancreas, their direct actions on basal and stimulated release of secretory protein were monitored *in vitro*. Prostaglandins E_2 and $F_{2\alpha}$ (10^{-8} to 10^{-5}M) did not alter the rate of basal secretion. At 10^{-5}M they did not affect the secretory response to either carbachol (10^{-5}) or dibutyryl cyclic AMP (10^{-3}). Similar results were noted for serotonin (10^{-7} to 10^{4}M). Therefore, it was concluded that, despite the effects on the vasoactive substances on fluid and electrolyte secretion from exocrine pancreas or salivary gland, these substances are without direct effect on the basal or stimulated release of protein from the pancreas.

0965 STIMULATION OF INTESTINAL SECRETION BY POLYPEPTIDE HORMONES. *(E.)* Barbezat, G. O. (VA Wadsworth Hosp., Los Angeles, Calif.). *Scand. J. Gastroenterol.* 8(22):1-21, 1973.

Electrolyte solutions containing phenol red as a non-absorbable marker were perfused through 30 cm Thiry-Vella loops of jejunum or ileum in dogs, and net movements of water and electrolytes were measured. Glucagon (30 g/kg-hr i.v.) caused net secretion of water and salt into the jejunum, while glucagon and pentagastrin reduced net water and salt absorption in both jejunum and ileum. Pure synthetic secretin did not alter net water and salt movements. In the second part of the study intestinal juice was collected from dogs by continuously pumping humidified air at 15 ml/min into the proximal end of the Thiry-Vella loop and collecting secretions from the distal end. The volume and electrolyte composition of the secretions were measured before, during and after stimulation with various polypeptides. Glucagon, pentagastrin, vasoactive intestinal polypeptide and gastric inhibitory polypeptide were all stimulants of gut mucosal secretion. Pure synthetic secretin and the octapeptide of cholecystokinin did not stimulate secretion. The responses to glucagon and pentagastrin in both jejunum and ileum were dose related, while the response to gastric inhibitory polypeptide was only dose related in the jejunum. Stimulation produced an increase in volume of fluid and output of electrolytes, whereas electrolyte concentration remained relatively constant. The composition of the secreted fluid was typical of the level of gut stimulated (high chloride-low bicarbonate in the jejunum, and low chloride-high bicarbonate in the ileum). The protein concentration of the juice dropped during the period of hormonal stimulation suggesting that the fluid was not a transudate. In dogs with 30 cm colonic Thiry-Vella loops, glucagon stimulated secretion, pure synthetic secretin and pentagastrin were ineffective. Colonic juice electrolyte concentration was affected little by stimulation. Neither glucagon nor pentagastrin alone induced diarrhea when infused in intact dogs in large doses for 8 hr. However, when given together, these hormones induced watery diarrhea in all dogs. This effect was not specific to this combination of hormones; simultaneous infusion of the octapeptide of cholecystokinin and pentagastrin also regularly induced diarrhea. It is postulated that these hormones may help regulate intestinal secretion in health, and in diseases characterized by excessive secretion into the bowel.

0966 PANCREATIC ACINAR CELLS: ACETYLCHOLINE-INDUCED MEMBRANE DEPOLARIZATION, CALCIUM EFFLUX AND AMYLASE RELEASE. *(E.)* Matthews, E. K.; Petersen, O. H.; Williams, J. A. (Dept. Pharmacol., Univ. Cambridge, England). *J. Physiol.* 234(3):689-701, 1973.

The effects of acetylcholine on the output of amylase, Ca^{2+} efflux and membrane potential of pancreatic acinar cells were measured in segments of mouse pancreas superfused *in vitro*. Amylase output was measured continuously using an on-line automated fluorimetric method. Ca^{2+} efflux was monitored by the release of $^{45}Ca^{2+}$ from pre-labelled tissue. Intracellular recordings of acinar transmembrane potentials were obtained with glass micro-electrodes.

In some experiments membrane potentials, and in others $^{45}Ca^{2+}$ efflux, were measured concomitantly with amylase release. Acetylcholine depolarized the acinar cells, increased tissue $^{45}Ca^{2+}$ efflux and raised amylase output, each with a similar dose-dependence, i.e. a maximal response at 10^{-5} M, threshold $< 10^{-8}$ M, and ED_{50} values of 0.7 X 10^{-7} M, 0.5 X 10^{-7} M, and 2 X 10^{-7} M for depolarization, amylase release, and $^{45}Ca^{2+}$ efflux, resp. In response to acetylcholine both depolarization and $^{45}Ca^{2+}$ efflux preceded or coincided with the increase in amylase output. Acetylcholine 10^{-5} M and $[K]_0$ 47 mM did not effect $^{45}Ca^{2+}$ efflux in the presence of atropine (3 X 10^{-6} M) but pancreozymin (0.3 u/ml) still elicited a marked increase in $^{45}Ca^{2+}$ release. These results suggest that the stimulatory action of acetylcholine on the pancreatic acinar cell involves, sequentially, a specific receptor-activated increase in membrane permeability, depolarization, Ca^{2+} mobilization and amylase release.

0967 PANCREATIC ENZYME RESPONSE TO SECRETIN AND CHOLECYSTOKININ-PANCREOZYMIN IN THE RAT.

(E.) Folsch, U. R.; Wormsley, K. G. (Maryfield Hosp., Dundee, Ireland). *J. Physiol.* 234(1):79-94, 1973.

A new technique has been devised for collecting pancreatic juice in anesthetized rats. The technique involves perfusion of the duodenum and is particularly suitable for analyzing characteristics of pancreatic enzyme secretion. To ensure stable secretory conditions, male Wistar rats were kept at 30 C. Different combinations of secretin and cholecystokinin-pancreozymin were given by continuous i.v. infusion. Maximal secretion of the pancreatic enzymes was observed with 60 Ivy units/kg-hr cholecystokinin-pancreozymin (amylase) or 120 Clinical units/kg-hr (trypsin) combined with 0.5 Clinical units/kg-hr (secretin). Pancreatic enzyme secretion in response to submaximal stimulation with cholecystokinin-pancreozymin caused significantly less secretion of pancreatic enzymes than in response to maximal stimulation. Pancreatic secretion of enzymes was poorly sustained during constant-rate stimulation with i.v. hormones at all dose rates. These results indicate that enzyme secretion was inhibited either because the stimulus became relatively ineffective or because there was interference with the processes involved in the synthesis or secretion of the enzymes. It is not certain whether the decreased enzyme secretion indicates a direct effect of the small intestinal stimulant hormones, their breakdown products or contaminants, and represents a form of tracyphylaxis due to inactivation of receptor sites, or is due to secondary hormonal or metabolic effects. The biphasic enzyme secretion dose-response patterns appear to be a property of the pancreatic enzyme-secreting cells themselves.

0968 EFFECT OF DIVERSION AND REPLACEMENT OF BILE ON PANCREATIC SECRETION.

(E.) Konturek, S. J.; Thor, P. (Med. Acad., Cracow, Poland). *Am. J. Dig. Dis.* 18(11):971-977, 1973.

Pancreatic bicarbonate and protein outputs were studied under basal conditions and in response to a variety of endogenous and exogenous stimuli in conscious dogs with biliary and pancreatic fistulas and with bile diverted and then replaced into the intestine. Infusion of bile into the duodenum and jejunum but not the ileum caused a marked increase in pancreatic protein secretion, and to a lesser degree in bicarbonate output, only in tests performed under basal conditions. Pancreatic dose-response curves to i.v. secretin and caerulein, to i.d. hydrochloric acid and amino acids, or to feeding liver meal were not significantly altered by the diversion and subsequent replacement of bile into the duodenum. It is suggested that the release of cholecystokinin or neuro-reflex stimulation of pancreas by the bile in the intestine may explain the bile stimulation of pancreatic secretion observed. These studies show that the actual increase of pancreatic secretion evoked by the instillation of bile into the duodenum or jejunum is most pronounced under basal conditions and concerns mainly protein outputs. The physiologic significance of bile stimulus to pancreatic secretion in the fasting state is not clear. It is noted, however, that, due to intermittent gallbladder contraction during interdigestive periods, small amounts of bile are released into the duodenum. Consequently, pancreatic secretory activity proceeds at a low rate even in the absence of food digestion.

0969 EFFECT OF TOLBUTAMIDE ON GLUCAGON SECRETION. II. STUDY IN ISOLATED AND PERFUSED RAT PANCREAS.

(Fr.) Loubatieres, A. L.; Alric, R.; Louratieres-Mariani, M. M.; Puech, R. (no affil.). *C. R. Soc. Biol. (Paris)* 166(12):1761-1764, 1972.

Isolated pancreas from Wistar rats fed *ad libitum* was perfused for 45 min with an isotonic solution containing 1.5 g/liter glucose. In one group of experiments the glucose concentration was then reduced to 0 g/liter, while in a second it was reduced to 1 g/liter. Addition of 0.4 mM tolbutamide in the absence of glucose significantly increased glucagon secretion of the pancreas for 3 min at most. A second increase occurred 30 min after addition of tolbutamide; this increase persisted even after there was no more tolbutamide in the perfusing solution. When glucose was present in the perfusing fluid in a concentration of 1 g/liter, a progressive increase in glucagon secretion occurred over the next 30 min; this increase also persisted after there was no more tolbutamide in the perfusing fluid. The presence or absence of glucose in the perfusing fluid is one of the factors which modify the extent to which cells in the islets of Langerhans react to tolbutamide. Therefore, it is absolutely essential to specify the glucose concentration when studying the effect of tolbutamide on glucagon secretion.

0970 COMPARISON OF SYNTHETIC AND NATURAL PORCINE SECRETINS ON HUMAN PANCREATIC SECRETION.

(E.) Farooq, O.; Sturdevant, R. A. L.; Isenberg, J. I. (Wadsworth VA Hosp., Los Angeles, Calif.). *Gastroenterology* 66(2):204-209, 1974.

The effect of graded intravenous doses of synthetic porcine secretin and natural porcine secretin on pancreatic secretion was examined in 6 healthy male subjects. Pancreatic secretion was also studied in 3 subjects after subcutaneous synthetic secretin. The doses of synthetic secretin were: 0.024, 0.047, 0.094, 0.188, 0.375, 0.75, and 1.5 μg/kg-hr. The doses of natural secretin were: 0.094, 0.188, 0.375, 0.75, 1.5, 3.0, and 6 U/kg-hr. Each dose was infused for 30 min. Calculated maximal response of bicarbonate output and secretin dose for one-half maximal response (D_{50}) were calculated for both synthetic and natural secretins from the means of the dose-response data. The dose-response curves with synthetic secretin and natural secretin were superimposable for: volume, bicarbonate concentration, and bicarbonate and protein output. The observed and calculated maximal responses for bicarbonate secretion were not significantly different between the 2 secretins. Subcutaneous synthetic secretin increased pancreatic secretion above basal for 3 hr. It was concluded that in man: (1) synthetic secretin and natural porcine secretin were of equal efficacy for bicarbonate secretion; (2) 1 μg of synthetic secretin was equivalent to approximately 3.86 U of natural secretin; (3) subcutaneous synthetic secretin was an effective stimulant of pancreatic bicarbonate secretion; (4) synthetic secretin was free of any observed side effects.

SECRETION AND METABOLISM

Hepatobiliary Tract

0988 METABOLIC FATE OF RAT AND HUMAN LIPOPROTEIN APOPROTEINS IN THE RAT. *(E.)* Eisenberg, S.; Windmueller, H. G.; Levy, R. I. (Natl. Inst. Arthritis, Metab., Dig. Dis., Bethesda, Md.). *J. Lipid Res.* 14(4):446-458, 1973.

The fate of ^{125}I-labeled apolipoproteins was studied *in vivo* in rats receiving i.v. injections of ^{125}I-labeled rat high-density lipoprotein and ^{125}I-labeled human high-density lipoprotein, low-density lipoprotein, very low-density lipoprotein. Plasma decay curves of rat and human high-density lipoprotein were exponential with similar half-lives in the circulation (11-12 hr). After injection, low molecular weight apolipoproteins (alanine of human high-density lipoprotein and fraction HS-3 of rat high-density lipoprotein) were found to redistribute to other lipoproteins, predominantly very low-density lipoproteins. Decay curves of individual high-density lipoproteins proteins were constructed after lipoprotein fractionation, delipidation, and polyacrylamide gel electrophoresis. The half-lives of the different high-density lipoproteins apoproteins were not identical. A major rat high-density lipoprotein protein (52% of total counts) had a circulating half-life of 12.5 hr. A circulating half-life of 8-9 hr was determined for 2 others while the half-life of several others was 11-12 hr. The half-life of 3 well-characterized human high-density lipoproteins apoproteins apolipoprotein-glutamine I, apolipoprotein-glutamine II, and apolipoprotein-alanine, were 13.5, 9.0, and 15.0 hr, resp. The fate of ^{125}I-labeled human very low-density lipoprotein and low-density lipoprotein apoproteins in rats was similar to that in humans. After injection of ^{125}I-labeled human very low-density lipoprotein into rats, apolipoprotein-glutamic acid and apolipoprotein-alanine rapidly transferred to rat high-density lipoprotein and were lost thereafter from the circulation from both very low-density lipoprotein and high-density lipoprotein. The apolipoprotein moiety of human very low-density lipoprotein moved metabolically to the low-density lipoprotein density range through a lipoprotein of intermediate density. Analysis of tissue radioactivity at time intervals after the injection of labeled lipoproteins suggests that the liver is important in the clearance of all lipoprotein preparations from plasma.

0989 GASTRIC CONTAMINATION BY SALIVARY MUCOUS SECRETIONS IN THE PYLOROUS-LIGATED RAT. *(E.)* Chayvialle, J. A.; Lambert, R. (E. Herriot H Hosp., Lyon, France). *Digestion* 8(6):497-508, 1973.

Contamination of the gastric juice of the rat by sulfated salivary mucosubstances was studied in pylorus-ligated male Wistar rats. The nondialyzable radiosulfate (NDRS) after proteolysis in saliva and gastric juice indexed the amount of sulfated mucosubstances present in them. The ligation of the esophagus evokes a strong decrease of the amount of NDRS in the gastric contents, while no significant variation of the NDRS is observed in the gastric wall. The simultaneous collection of saliva and gastric juice in the presence of an esophageal catheter shows that the NDRS in pure gastric juice reaches only 5% of the values in saliva. A higher percentage is obtained when the secretions are collected above (salivary) and under (gastric) a forestomach-fundus ligation, but the NDRS in pure gastric juice is still less than 20% of the amount collected in saliva. Histochemical and autoradiographic studies on the salivary glands did not reveal any sulfated components in the parotid, submaxillary, and major sublingual glands, while they were present in the accessory mucous glands. This was confirmed by the lack of effect of a salivary ducts ligation on the non-dialyzable radiosulfate content of the gastric juice. It is concluded that accessory mucous glands in the oral cavity play a major role in the mucous contamination of the gastric juice.

0990 THE RELATION OF PLASMA GASTRIN TO THE CIRCADIAN RHYTHM OF GASTRIC ACID SECRETION IN MAN. *(E.)* Moore, J. G.; Wolfe, M. (Univ. Utah Coll. Med., Salt Lake City). *Digestion* 9(2):97-105, 1973.

The relation of the circadian rhythm of basal acid secretion to fluctuations in plasma gastrin levels was studied in 10 healthy, young (ages 22-27) male volunteers from whom 24-hr basal gastric acid collections were obtained. The hourly secretory pattern, which described a circadian periodicity (low morning, high evening acid rates), was compared with mean plasma gastrin levels obtained at 4-hr intervals. No rhythm in plasma gastrin was detected over the 24-hr collection period and the circadian rhythm of basal and output is not due to fluctuations in the plasma gastria level.

0991 EFFECT OF PENTAGASTRIN AND SECRETIN ON GASTRIC MUCUS SECRETION IN CONSCIOUS CATS.

(E.) Vagne, H.; Argier, M. C. (Hosp. E. Herriot, Lyon, France). *Gastroenterology* 65(5):757-763, 1973.

Gastric mucus secretion was studied simultaneously with acid and pepsin secretion during pentagastrin and secretin stimulation in 3 conscious cats with Heidenhain pouch (HP) and gastric fistula (GF). Pentagastrin (32 μg/kg/hr) produced an increase of the volumes from GF and HP. Secretin (3 U/kg/hr) added to pentagastrin produced no change of the volume of gastric juice secreted by HP and a slight increase from GF. Acid output was strongly stimulated by pentagastrin. Secretin induced no change of acid output from HP and a slight decrease from GF. Pepsin concentration decreased during pentagastrin infusion and increased during secretion. Pepsin output increased during pentagastrin stimulation in GF and HP juices. Uronic acid concentration decreased in GF and HP juices during pentagastrin stimulation and increased with secretin. The ration of uronic acid to pepsin did not differ from basal during pentagastrin stimulation, while it decreased when secretin was added. Uronic acid output increased in GF and HP secretions during pentagastrin stimulation. Fucose and galactose concentrations fell significantly during pentagastrin infusion and showed a small increase during secretin. Fucose and galactose outputs from HP increased above basal level during pentagastrin stimulation. These results show that mucus secretion may occur independently of acid secretion and that gastrointestinal hormones play a role in regulating mucus secretion.

0992 IMPAIRMENT OF HEPATIC UPTAKE OF RIFAMYCIN ANTIBIOTICS BY PROBENECID, AND ITS THERAPEUTIC IMPLICATIONS.

(E.) Kenwright, S.; Levi, A. J. (Clin. Res. Ctr., Harrow, England). *Lancet* (7843):1401-1405, 1973.

Bilirubin uptake by the liver as affected by rifamycins and probenecid was studied in Homozygous Gunn rats. Hepatic uptake of BSP was studied in Sprague-Dawley rats. Both probenecid and rifamycins greatly prolong the initial plasma clearance for BSP *in vivo*, but neither compound displaced BSP from ligandin or Z acceptor proteins *in vitro*, indicating that competition for binding to these proteins cannot be the main mechanism for the impaired hepatic uptake of BSP found *in vivo*. Rifamycin-SV and probenecid had similar effects on bilirubin concentrations in the liver-cell fractions of Gunn rats; *in vivo*, supernatant, ligandin, and Z fraction bilirubin levels were all reduced by similar proportions. *In vitro* addition of very high doses of each drug to Gunn supernatant displaced bilirubin selectively from Z protein. Therefore, both BSP and bilirubin hepatic uptake is impaired by these drugs at an earlier step than the acceptor proteins, possibly at the plasma membrane level, which suggests that the drugs may compete at the same site. The uptake of rifamycin-SV and ^{14}C-rifampicin into the liver cell was depressed by probenecid. Thus, more of the antibiotic would be available for distribution to other tissues. Healthy male subjects (6, aged 24-40 yr), each received rifampicin (365 μmole p.o. twice, 2 or 3 days apart). Probenecid was administered 2 g at 20 min before the antibiotic and 1.5 g at 6 hr after. The serum-rifampicin levels were raised after treatment with probenecid, and the clearest effects of probenecid were noted before the second probenecid dose. It is suggested that a single-dose regimen of probenecid and rifampicin may be of therapeutic value in reducing rifampicin requirement in the treatment of tuberculosis.

0993 STUDY OF Y AND Z, TWO CYTOPLASMIC BILIRUBIN BINDING PROTEINS. THEIR DEVELOPMENT IN THE LIVER OF FOETAL AND NEWBORN WISTAR AND GUNN RATS.

(E.) Foliot, A.; Housset, E.; Ploussard, J. P.; Petite, J. P.; Infante, R. (Unit Biol. Res. Anim. Exp. Tech., I.N.S.E.R.M., Paris, France). *Biomedicine* 19(11):488-491, 1973.

The development of the hepatic cytoplasmic proteins Y and Z, recently identified as able to accept and/or carry bilirubin in the hepatocyte, was studied in Wistar rats and in Gunn rats (Wistar strain mutant) with inherited lack of glucuronyl-transferase. The protein fractions were measured in livers of 18- and 21-day old fetuses and rats aged 5, 10, 20, 30, and 60 days. In Wistar rats, Z protein (assessed by BSP binding) appears on day 21 of fetal life. After birth, Z increases rapidly until day 10, then increases more slowly and reaches adult level in about 20 to 30 days. The Y protein appears after birth and increases steadily, but reaches mature levels only in 60 days. In Gunn rats, Z protein is present on day 18 of fetal life. Its course of maturation then anticipates the course observed in Wistar rats. Y protein appears on day 20 of fetal life and reaches mature values on the 30th day after birth. There was no significant difference between the protein levels for the adults of the two strains. Because of high concentration and early presence in Gunn rat fetuses, it is suggested that bilirubin may stimulate Y and Z synthesis in the liver.

0994 EFFECTS OF LIPID PEROXIDATION ON ACTIVITIES OF DRUG-METABOLIZING ENZYMES IN LIVER MICROSOMES OF RATS.

(E.) Kamataki, T.; Kitagawa, H.; (Fac. Pharm. Sci., Chiba, Japan). *Biochem. Pharmacol.* 22(24):3199-3207, 1973.

The effects of lipid peroxidation on the activities of drug-metabolizing enzymes was investigated using livers from male Wistar rats. Increasing the ferrous ion increment in the incubation mixture increased lipid peroxidation and decreased ethylmorphine N-demethylating activity. EDTA (0.02 mM) stimulated apparent activity of aminopyrine N-demethylation up to about 2-fold. The activity gradually declined with increasing EDTA concentrations. The stimulation of aminopyrine N-demethylation correlated closely with the decrease in formation of lipid peroxide. Similar effects of EDTA were noted using ethylmorphine as a substrate. Ethylmorphine N-demethylation was stimulated by addition of inhibitors of lipid peroxidation. When microsomes were preincubated for varying lengths of time with a NADPH-generating system, a marked decrease in the demethylation of codeine and a concomitant increase in lipid peroxidation were observed. These results indicate that stimulation of lipid peroxidation delays the rate of drug oxidation and, conversely, that inhibition of lipid peroxidation accelerates that rate. While testing the effects of EDTA on the rate of ethylmorphine N-demethylation and lipid peroxidation, ethylmorphine inhibited lipid peroxidation with increasing concentration, 10 mM ethylmorphine inhibiting lipid peroxidation by about 70%. In the presence of complete inhibition of lipid peroxidation by EDTA, the rate of ethylmorphine N-demethylation was markedly increased. The apparent stimulation by EDTA was more pronounced if low concentrations of ethylmorphine were employed. Thus it is evident that the low concentrations of ethylmorphine only partly inhibit lipid peroxidation. It is assumed that addition of EDTA to the incubation mixture causes changes in the inhibition constants of drug-metabolizing enzymes by SKF 525-A, since EDTA produced apparent activation of drug-metabolizing enzymes and SKF 525-A has an ability to block lipid peroxidation. When ethylmorphine, aminopyrine and aniline were used as substrates, EDTA in all cases produced changes in the inhibition constants of SKF 525-A to smaller values.

0995 EFFECT OF STARVATION ON THE QUANTITATIVE CELL STRUCTURE OF RAT LIVER CELLS. I. ABSOLUTE STARVATION AND REFEEDING. *(Ger.)* Rohr, H. P.; Brunner, H. R.; Rasser, Y. M.; von Matt, C. A.; Riede, U. N. (Inst. Pathol., Univ. Basel, Switzerland). *Beitr. Pathol.* 149(4):347-362, 1973.

Morphometric analyses were performed on liver tissue from 10-week-old male Fisher rats which had been given water but no food for 3, 6, and 9 days and from rats which had been starved for 9 days and were then refed for 3 days. After 9 days of starvation the cell volume had decreased by 50%. The mitochondrial volume increased 7-fold, but the number of mitochondria in each liver cell decreased. After 3 days of starvation the area of the cristae per unit volume of mitochondria was decreased. A pronounced decrease occurred in the area of the smooth and rough endoplasmic reticula after 6-9 days of starvation. The percentage volume of lysosomes per liver cell doubled after 6 days of starvation and then gradually decreased. Morphological parameters of the liver cells normalized when starved rats were refed for 3 days, but the volume of liver cells and the area of the rough endoplasmic reticulum increased to values above normal. On the basis of these findings, changes in the ultrastructure of liver cells occurring as a result of starvation are classified into 2 stages. The first is a compensation stage which lasts until the 6th day of starvation and is characterized by retention and development of only those cell structures necessary for continued cell vitality. The increases in mitochondrial volume are apparently not only a swelling, but may also be due to membrane synthesis and changes in mitochondrial energy metabolism. The decompensation stage, which sets in after 6-9 days of starvation, is characterized by cellular autophagy and the dissolution of cell organelles in the hyaloplasm. The integrity of mitochondrial membranes is lost, and the mitochondria swell.

SECRETION AND METABOLISM

Intestine

1064 EFFECT OF FASTING ON CARBOHYDRATE MOIETY OF GUINEA PIG INTESTINAL BRUSH BORDERS. *(E.)* Bouhours, J. F.; Andre, F.; Guignard, H.; Lambert, R. (Hosp. Edouard Herriot, Lyon, France). *Digestion* 9(4):309-316, 1973.

Albino guinea pigs subjected to fasting for 2 days were compared with controls subjected to fasting for 1 day and fed for 1 day. Weight, protein content, and sucrase activity of intestinal mucosa were lowered. Analysis of carbohydrate moiety of isolated brush borders by gas-liquid chromatography and colorimetric methods revealed an increase of fucose, sialic acid, and sulfate with fasting conditions mainly in the proximal part of intestine. Glucose, however, tended to decrease, and other neutral and amino sugars did not change. It is concluded that fucose, sialic acid, and sulfate groups increase in the cell membrane when the cell-renewal rate decreases.

1065 INTESTINAL VERSUS HEPATIC CONTRIBUTION TO CIRCULATING TRIGLYCERIDE LEVELS. *(E.)* Cenedella, R. J.; Crouthamel, W. G.; Mengoli, H. F. (West Virginia Univ. Med. Ctr., Morgantown). *Lipids* 9(1):35-42, 1974.

Using i.v. injected [2-^{3}H] glycerol, measurements were made of the kinetics of appearance and disappearance of circulating [^{3}H] labeled triglyceride in male Sprague-Dawley rats fed a fat-free diet containing no orotic acid (controls) or 2% orotic acid. Following injection of [^{3}H] glycerol, more time is required for the initial appearance of [^{3}H] triglyceride in the circulation of orotic acid-treated rats than controls. The sustained entry of triglyceride into the circulation of orotic acid-fed rats was only one-half times as rapid as that seen for control rats. About 10% as much [^{3}H] triglyceride entered the circulation of the orotic acid-treated rats as compared with controls. However, the clearance of [^{3}H] triglyceride from the circulation of the orotic acid-fed rat was only about one-half times as rapid as that of the control rat. This apparently is due to differences between the lipoproteins produced by the intestines and liver, rather than to changes in the ability of the orotic acid fed animal to clear lipoprotein-triglyceride from the circulation. Labeled lipoproteins taken from controls and injected into orotic acid-treated rats were cleared from the circulation more than twice as rapidly as those taken from orotic acid-fed rats and injected into controls. Considering the measured levels of plasma triglyceride synthesis and the slower turnover of the triglycerides produced by the orotic acid fed rat, this study indicated that the intestines supply 20% or more of the total plasma triglyceride in the absence of dietary fat.

1066 MEASUREMENT OF ENDOGENOUS RELEASE OF CHOLECYSTOKININ BY RADIOIMMUNOASSAY. *(E.)* Reeder, D. D.; Becker, H. D.; Smith, N. J.;

Rayford, P. L.; Thompson, J. C. (Dept. Surg., Univ. Texas Med. Branch, Galveston). *Ann. Surg.* 178(3):304-310, 1973.

A radioimmunoassay technique has been developed for measuring circulating levels of endogenous cholecystokinin in man and in dogs. There is no cross reaction with gastrin. Using this assay increases were detected in serum concentrations of cholecystokinin following a fatty meal in man, and during application of acid or an amino acid mixture to small bowel mucosa in dogs. Concentrations of cholecystokinin were almost the same in duodenal and jejunal mucosa and were significantly higher than in the ileal mucosa. This radioimmunoassay for cholecystokinin should be useful in delineating the overlapping actions of the gastrointestinal hormones in physiologic studies.

1067 ACID LOSS IN THE HUMAN DUODENUM: VOLUME CHANGE, OSMOLAL LOSS, AND CO$_2$ PRODUCTION IN RESPONSE TO ACID LOADS. *(E.)* Winship, D. H.; Robinson, J. E. (Univ. Missouri Sch. Med., Columbia). *Gastroenterology* 66(2):181-188, 1974.

Isotonic hydrochloric acid solutions of different pH were infused into the proximal duodena of normal males to investigate the relationship between the amount of acid infused, acid loss from the duodenum, and chemical neutralization of acid in the duodenal lumen. From samples aspirated at 15 cm and 30 cm downstream, some relationships between acid load, acid loss, and chemical neutralization of acid in the duodenal lumen were studied. At infusions with solutions of pH 1, pH 2, and pH 3, gain of fluid was recognized; the gain in the lumen increased progressively with increase in infused acid load. Duodenal fluid Pco$_2$ levels increased markedly during pH 1 and pH 2 infusions; values up to 700 mm Hg were recorded. Osmolality of duodenal fluid decreased as a result of the neutralizing reaction between acid and bicarbonate during pH 2 and pH 1 infusions. The major changes were observed in the proximal duodenal segment; Pco$_2$, and osmolality reverted toward normal in the distal segment. Level of Pco$_2$ and degree of decrease in osmolality were similarly related to the amount of acid lost from the duodenum and exhibited a strong mutual correlation, reflecting their common origin in the chemical neutralization of HCl with endogenous bicarbonate. Almost all acid loss occurred in the proximal duodenal segment. If acid entered the distal segment it evoked a further secretion of fluid; otherwise, net absorption occurred in the segment. It seems likely that the fluid gained in the lumen neutralized the acid.

068 IMMUNE RESPONSES IN INTESTINAL TISSUE TO PARTICULATE ANTIGENS. DEVELOPMENT OF CELLS FORMING DIFFERENT CLASSES OF ANTIBODY IN PRIMARY AND SECONDARY RESPONSES. *(E.)* Robertson, P. W.; Cooper, G. N. (Sch. Microbiol., Univ. New South Wales, Kensington, Australia). *Aust. J. Exp. Biol. Med. Sci.* 51(5):575-587, 1973.

Characteristics of immune responses resulting from antigenic stimulation via the intestinal epithelium were examined by enumerating rosette-forming cells synthesizing IgM, IgG, and IgA antibodies. These cells arose in local and peripheral lymphoid tissues in both primary and secondary responses. The primary response of mesenteric lymph nodes was similar in general to that observed in the spleen or other lymph nodes when antigen is given parenterally, showing the characteristic change from IgM to IgG antibody formation. In the intestinal submucosa and lamina propria IgA-rosette-forming cells were the most numerous, but a significant IgG response was also noted. Following immunization via the intestinal route, IgA-rosette-forming cells also appeared in the spleen. This route of immunization primes animals to respond to later antigenic stimulation given either via the intestine or parenterally. This primed state lasts at least 14 weeks. The greatest secondary response occurred in the mesenteric lymph nodes where IgM-rosette-forming cells predominate. In the intestinal lamina propria and submucosa the IgM-rosette-forming cells secondary response was substantially greater than that of IgG- and IgA-rosette-forming cells. Priming via the intestinal route led to a significant IgA-rosette-forming cells response in the spleen, irrespective of whether the second injection was i.v. or given intestinally. This suggests that the entry of antigen from the intestine gives rise to a substantial population of memory cells in the spleen, committed to IgA antibody formation. Whether these cells develop in the spleen or in the intestinal tissues and subsequently migrate to the spleen is open to question.

1069 DISACCHARIDASES IN THE SMALL INTESTINE OF THE MOUSE: NORMAL DEVELOPMENT AND INFLUENCE OF CORTISONE, ACTINOMYCIN D, AND CYCLOHEXIMIDE. *(E.)* Moog, F.; Denes, A. E.; Powell, P. M. (Dept. Biol., Washington Univ., St. Louis, Mo.). *Dev. Biol.* 35(1):143-149, 1973.

The development of maltase, sucrase, and lactase activity was examined in the small intestine of mice. Maltase increased during 2 days before birth and then remained unchanged for 14 days, after which activity surged throughout the intestine. Sucrase was absent during the first 14 days, but then rose in a pattern similar to maltase. Both enzymes rose faster in the proximal third of the intestine. Lactase, which is high in the infant intestine, falls after 12 days in the proximal segment, but only after 16 days in the more posterior segments. Cortisone, administered at 8 days, caused maltase activity to rise for at least 72 hr. At 4 days the same treatment caused an increase for only 48 hr. Sucrase activity was elicited by cortisone at 8 days, but not at 4. Between days 10 and 13, both actinomycin D and cycloheximide evoked significant increases of both maltase and sucrase activity in all regions of the intestine. When administered in concert with cortisone, actinomycin D inhibited the stimulatory influence of the hormone on sucrase. Significant inhibition of maltase activity occurred only in the mid third of the intestine. Cycloheximide did not interfere with the cortisone effect. No additive effects between hormone and antibiotics were observed. These facts suggest that the infant epithelium may, under normal conditions, be restrained from undergoing maturation before the sensory and neuromuscular systems have differentiated sufficiently to permit the young animals to seek their own food independently of the mother. This suggests that the common action of the agents used in this study may have been to inhibit a repressor needed to preserve the infant condition.

1070 PATHOPHYSIOLOGICAL RESPONSE OF RABBIT JEJUNUM TO ESCHERICHIA COLI ENTEROTOXIN.

(E.) Sherr, H. P.; Banwell, J. G.; Rothfeld, A.; Hendrix, T. R. (Johns Hopkins Univ., Sch. Med., Baltimore, Md.). *Gastroenterology* 65(6):895-902, 1973.

A soluble cell-free entertoxin with secretory activity in the rabbit loop was prepared from a serotype of *Escherichia coli* isolated from an adult Indian patient with acute undifferentiated diarrhea. *E. coli* enterotoxin-stimulated jejunal secretion was maximal within 30 min of exposure, compared with a gradual increase in the rate of secretion after cholera toxin exposure. The electrolyte composition of the secreted fluid was similar to that of an electrolyte solution which had come to equilibrium within the jejunal lumen and to fluid secreted in response to cholera toxin exposure. The blood to lumen unidirectional flux of ^{22}Na and $^{3}H_2O$ increased significantly after exposure to both enterotoxins, while the lumen to blood flux did not change. Active transport of glucose and glycine after *E. coli* exposure decreased when compared with the unstimulated intestine, suggesting that *E. coli* enterotoxin or closely associated soluble products alter active transport processes as well as stimulate secretion. Thus, replacement with oral glucose-glycine solutions may not be particularly useful in acute undifferentiated diarrhea due to toxigenic *E. coli*. The similar effects on fluid secretion and unidirectional fluxes observed after *E. coli* and cholera enterotoxin exposure suggest stimulation of a common secretory process. However, differences in active transport-mediated absorption of glucose and glycine indicate a fundamental difference in the physiological activity of the molecule or associated soluble products.

1071 CHARACTERIZATION OF ILEAL VITAMIN B_{12} BINDING USING HOMOGENEOUS HUMAN AND HOG INTRINSIC FACTORS.

(E.) Hooper, D. C.; Alpers, D. H.; Burger, R. L.; Mehlman, C. S.; Allen, R. H. (Washington Univ. Sch. Med., St. Louis, Mo.). *J. Clin. Invest.* 52(12):3074-3083, 1973.

Homogenous human intrinsic factor and hog intrinsic factor isolated by affinity chromatography were used to study [^{57}Co]-vitamin B_{12} binding to ileal mucosal homogenates. Human intrinsic factor-vitamin B_{12} and hog intrinsic factor-vitamin B_{12} were bound to human, monkey, hog, dog, rabbit, mouse, hamster, and guinea pig ileal, but not jejunal, homogenates in amounts significantly greater than free B_{12} or vitamin B_{12} bound to 5 other homogenous B_{12}-binding proteins. Only intrinsic factor-mediated B_{12} binding was localized to ileal homogenates and was inhibited by ethylenediaminetetraacetic acid. Values for the association for the various ileal homogenates and human intrinsic factor-B_{12} and hog intrinsic factor-B_{12} ranged from $0.3 \times 10^{9}M^{-1}$ to $13.0 \times 10^{9}M^{-1}$. Apparent differences in the association constant for human intrinsic factor-B_{12} and hog intrinsic factor-B_{12} existed in most species. The number of ileal intrinsic factor-B_{12} binding sites/g (wet weight) of ileal mucosa ranged from 0.3 to 10^{12} to 4.9×10^{12}. The same value was always obtained with human intrinsic factor-B_{12} and hog intrinsic factor B_{12} for any given homogenate preparation. Excesses (100-fold) of free B_{12} or human intrinsic factor and hog intrinsic factor devoid of B_{12} did not significantly inhibit human intrinsic factor-B_{12} or hog intrinsic factor-B_{12} binding to human and hog ileal homogenates. Experiments performed with homogeneous intrinsic factor indicated that gastric factors other than intrinsic factor are not required for B_{12} binding to ileal binding sites. The mechanism of ileal intrinsic factor-B_{12} binding differs from that of free B_{12} or of B_{12} bound to non-intrinsic factor-B_{12} binding proteins. Human intrinsic factor and hog intrinsic factor have different structures. Human intrinsic factor-B_{12} and hog intrinsic factor-B_{12} bind to the same ileal binding sites. Human and hog ileal intrinsic factor-B_{12} binding sites bind free B_{12} and human and hog intrinsic factor devoid of B_{12} poorly, if at all.

1072 INFLUENCE OF THE PROTEIN CONTENT OF A MEAL ON POSTPRANDIAL PH AND PCO_2 IN THE HUMAN DUODENUM.

(E.) Rune, S. J. (Gentofte Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 8(7):605-608, 1973.

The pH and pCO_2 were measured in small samples of duodenal contents, aspirated from the second part of the duodenum each 15 min for 4 hr, after a meal. The study comprised 10 patients, 4 with duodenal ulcer and 2 with X-ray negative dyspepsia. Each of the 10 was given a liquid test meal on 2 subsequent days. The protein content was 7 cal% on one day and 25 cal% on the other, in randomized order. During the second and the third postprandial hr the duodenal pH was around 0.7 units lower after the high-protein than after the low-protein meal, while no significant difference was found in the first and fourth hr. The pCO_2 was very high after both meals, around 500 mm Hg, and was slightly higher after the high-protein meal than after the low, during the third and fourth hr. It is concluded that the influence of the protein content of the meal on duodenal pH must be due to the different titratable acidity of the gastric contents more than to the difference in pH of these contents.

1073 DUODENAL IMMUNOGLOBULIN LEVELS IN THE FIRST TWO YEARS OF LIFE.

(E.) Ansaldi, N.; Musso, A.; Marengo, M. L., Santini, B. (Clin. Pediatr., Univ. Torino, Italy). *Biomedicine* 19(10): 435-437, 1973.

Immunoglobulin levels, IgA, IgG, and IgM, in duodenal juice were studied in 71 healthy infants, aged 0-2 yr. Comparison was made to a group of 19 children, aged 2-9 yr. During the first week of life only IgG was constantly present in the jejunal juice at a concentration which proved constant at all the ages studied. The youngest child in which IgA and IgM were found was 7 days old. IgA increased in quantity from 8-10 days, reaching constant values in the second half of the first year of life. IgM concentrations increased in a more rapid and uniform way after the first week till the second year of life. Later IgM content fell rapidly and significantly to values constant for subsequent ages studied. Thus it is concluded that IgG is much the same in concentration for all ages of life, IgA increases during the first year and then remains constant, and IgM follows a 2-phase course, increasing the first 2 years and then decreasing to remaining life values. It is suggested that the lack of IgA and IgM in the eonate duodenal juice may explain the high incidence of infections at that age mostly due to Gram egative bacteria. Whether the variation of the pattern of the jejunal IgM corresponds to modifications of the antigenic composition of the intestinal tract or to a modification in the type of the subject's antibody response is unclear. It is suggested that these data may be useful in immunological investigations of children with gastrointestinal diseases.

GENERAL

1096 FAILURE OF ISCHEMIA TO BREAK THE DOG'S GASTRIC MUCOSAL BARRIER. *(E.)* Davenport, H. W.; Barr, L. L. (Dept. Physiol., Univ. Michigan, Ann Arbor). *Gastroenterology* 65(4):619-624, 1973.

Vagally denervated (Heidenhain) pouches of the dog's oxyntic gland area of the stomach were irrigated with 100 mN HCl. Net fluxes of hydrogen and sodium ions, together with aminopyrine clearances, were measured. An increase in output of sodium ions and an increase in disappearance of hydrogen ions, in absence of secretion, were studied as possible measures of damage to the gastric mucosal barrier. Ischemia was produced by repeated injection of vasopressin (20 U every 30 min, s.c.), by a single hemorrhage (30% of blood volume), by repeated hemorrhages holding the dog's mean arterial blood pressure at 80 mm Hg, and by infusion of vasopressin (4 U/hr, i.v.) or norepinephrine (2-μg base/kg-hr). Infusion of vasoconstrictor drugs was combined with infusion of histamine (50-μg base/kg-hr), bethanechol chloride (50μg/kg-hr), or pentagastrin (8μg/kg-hr). Ischemia lasting 4, 5, or 6 hr had no effect on the integrity of the gastric mucosal barrier. Repeated injection of vasopressin, s.c., or a single, rapid hemorrhage did not induce ischemia lasting longer than 5 to 6 hr. When histamine or bethanechol and pentagastrin were given, the vasoconstrictor drugs were unable to cause lasting mucosal ischemia.

1097 MEASUREMENT OF DUAL HEPATIC BLOOD FLOW IN AWAKE PATIENTS. *(E.)* Strandell, T.; Erwald, R.; Kulling, K. G.; Lundbergh, P.; Marions, O.; Wiechel, K. L. (St. Erik Hosp., Stockholm, Sweden. *Appl. Physiol.* 35(5):755-761, 1973.

Dual hepatic blood flow was measured in 8 patients (6 men and 2 women with overt or suspect hepatic, biliary, or pancreatic disease) in whom a portal vein catheter was introduced through the reopened umbilical vein for direct selective portography. By use of a multiple-catheter technique blood flows were measured by constant infusion of indicator in the splenic artery, splenic vein, or the superior mesenteric vein. The concentration of indicator was measured in blood from the splenic vein, the right and left portal vein branches, a hepatic vein, and peripheral artery. ^{133}Xe was preferred as indicator and its mixing with blood within the main portal trunk was generally satisfactory. The equilibration over the liver took 4 min and the portal and hepatic vein blood flows were reproduced with an error of 5.5 and 8.1%, resp. Hepatic vein blood flows corresponded well to values obtained by the Bradley technique. Portal vein blood flow varied from 0.82 to 2.00 liters/min and hepatic artery flow from 15 to 56% of total hepatic flow. The 2 patients in whom no hepatic or abdominal disease could be proved had low hepatic artery flow values.

1098 CARDIOVASCULAR EFFECTS OF BLOOD BORNE MATERIAL RELEASED FROM THE CAT SMALL INTESTINE DURING SIMULATED SHOCK CONDITIONS. *(E.)*

Haglund, U.; Lundgren, O. (Dept. Physiol., Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 89(4):558-570, 1973.

Cardiac performance was studied in 17 cats during and after a mimicked shock situation in the small intestine (regional hypotension at 35 mm Hg during nervous vasoconstrictor fiber activation). Aortic blood flow was measured with an electromagnetic flow probe around the ascending aorta and, in some experiments, maximal dP/dt of the left ventricle was also followed. Upon restoration of intestinal perfusion pressure after a 2 hr "shock" period a rapid reduction of aortic flow occurred due to a decreased stroke volume. Concomitantly maximal dP/dt was reduced in the face of an unchanged central venous pressure and left end diastolic pressure. This decline of cardiac performance could be prevented by substituting, during the first post-hypotensive min, the intestinal venous blood with fresh blood from a healthy donor animal. However, when the shed intestinal venous blood was retransfused, a rapid decline of cardiac performance was evident. The reduced cardiac function was accompanied by an unchanged or slightly elevated total peripheral resistance. It is proposed that substances released from the "shocked" intestine cause a rapid and pronounced depression of cardiac function.

1099 COLLECTION OF LYMPH FROM DOG JEJUNAL ALLOTRANSPLANT. I. CELL TRANSFORMATION AND LYMPHOCYTOTOXICITY AGAINST THE HOST. *(E.)*

Olszewski, W.; Plucinski, S. (Exp. Clin. Med. Ctr., Polish Acad. Sci., Warsaw). *Eur. Surg. Res.* 5(4):311-319, 1973.

To study the changes in jejunal allograft lymph reflecting changes in the rejected transplant, an experimental setting was designed in dogs consisting of a segmental transplant of the jejunum to the neck and an external lymphatic fistula of the graft. Cellular studies of graft lymph from the 5 recipients revealed the appearance of blast cells on day 2 and degenerative forms of lymphocytes on day 5. Serological studies revealed increasing cytotoxic titers to the host lymphocytes from the 2nd day on. Peak values were reached at least 2 days before clinical signs of graft rejection were seen. This study proves the existence of an activating immunological response of the allografted intestinal lymphoid tissue (a graft *versus* host reaction in intestinal allotransplants).

1100 ENZYMATIC DEAMIDATION OF THE C-TERMINAL TETRAPEPTIDE AMIDE OF GASTRIN BY MAMMALIAN TISSUES. *(E.)*

Walsh, J. H.; Laster, L. (Natl. Inst. Arthritis Metabolic Dis., Bethesda, Md.). *Biochem. Med.* 8(3):432-449, 1973.

An amidase activity was detected in male Sprague-Dawley rat tissue which catalyzes deamidation of the phenylalanine amide of the biologically active C-terminal tetrapeptide amide fragment of gastrin (Try-Met-Asp-Phe-NH$_2$) to produce the biologically inactive tetrapeptide free acid. Because an interfering aminopeptidase that acts on the C-terminal tetrapeptide amide was widespread in rat tissues, *N*-acylated t-butyloxycarbonyl (BOC)-tetrapeptide amide was used as the substrate for studying the amidase activity. Identification of BOC-tetrapeptide free acid as a product of the amidase reaction was achieved by thin-layer chromatography. The reaction product was a substrate for carboxypeptidase A, which catalyzes liberation of phenylalanine from BOC-tetrapeptide free acid but not from BOC-tetrapeptide amide. A quantitative assay was developed to measure the generation of BOC-tetrapeptide free acid; this product and ammonia were produced in equivalent amounts during the reaction. The enzyme activity was concentrated in the microsomal cell fraction. The pH optimum for the reaction was approximately 6.7. Liver was a rich source of the amidase activity in the rat; this activity was also present in small intestinal mucosa, stomach mucosa, and pancreas of the rat and of the hamster, cat, and dog. Another enzymatic activity, most abundant in rat kidney, was found to catalyze hydrolysis of the peptide bond between methionine and aspartic acid of BOC-tetrapeptide amide. The amidase activity and the peptidase activity identified in the kidney may contribute to the inactivation of gastrin or of its biologically active degradation products *in vivo*.

1101 VASCULAR REACTIONS IN THE SMALL INTESTINE DURING VASODILATATION. *(E.)*

Biber, B.; Fara, J.; Lundgren, O. (Dept. Physiol., Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 89(4):449-456, 1973.

Reactions within the consecutive vascular sections of the small intestine of the cat were studied in 25 cats during vasodilatations induced by secretin and cholecystokinin, infused intraarterially or released endogenously, or by transmural electrical field and mucosal mechanical stimulations. All these potentially physiological stimuli evoked a response pattern similar to that of intraarterially infused 5-hydroxytryptamine and characterized by a relaxation of the resistance vessels as well as of the precapillary sphincters, as reflected in an increased capillary filtration coefficient. A small increase of regional blood volume was also observed during most vasodilatations. On the basis of these experiments it is impossible to exclude any of the above mentioned mechanisms in a discussion of the cause of the functional hyperemia of the gut. It is proposed that this vasodilatation depends partly on release of intestinal hormones, partly on local mechanisms evoked by mechanical and possibly also by chemical stimulation of the intestinal mucosa.

1102 THE EFFECTS OF E AND A PROSTAGLANDINS ON GASTRIC MUCOSAL BLOOD FLOW AND ACID SECRETION IN THE RAT. *(E.)* Main, I. H. M.; Whittle, B. J. R. (Dept. Pharmacol., Univ. London, England). *Br. J. Pharmacol.* 49(3):428-436, 1973.

The effects of prostaglandins E_1, E_2, A_1 and A_2 on gastric acid secretion and mucosal blood flow were studied by means of a [^{14}C]-aniline clearance technique in anesthetized female rats. During i.v. administration of these prostaglandins, in doses which almost completely inhibited pentagastrin- and histamine-induced acid secretion, a fall in clearance was observed. Clearance/unit acid secretion increased during prostaglandin administration, precluding a primary reduction in mucosal blood flow as the mechanism of the antisecretory action. Prostaglandins increased clearance during basal secretion, indicating a direct vasodilator effect on the gastric mucosa. Endogenous prostaglandins probably contribute to functional vasodilatation in the gastric mucosa. Exogenous prostaglandins, in particular the orally effective, the 15-methyl and 16,16-dimethyl analogues of prostaglandin E_2, may be of clinical value in the treatment of peptic ulcer.

1103 CHARACTERIZATION OF RAT LIVER SUBCELLULAR MEMBRANES. *(E.)* DeHeer, D. H.; Olson, M. S.; Pinckard, R. N. (Univ. Arizona Coll. Med., Tucson). *J. Cell Biol.* 60(2):460-472, 1974.

The effect of acute liver necrosis on the production of autoantibodies to all subcellular membranes and the reaction of these autoantibodies with unique autoantigenic determinants on each membrane was studied in adult Wistar rats. The induction of acute hepatocellular necrosis in rats resulted in the production of complement fixing, IgM autoantibodies directed toward inner and outer mitochondrial membranes, microsomal membrane, lysosomal membrane, nuclear membrane, cytosol, but not to plasma membrane. Utilizing selective absorption procedures it was demonstrated that each subcellular membrane fraction possessed unique autoantigenic activity with little or no cross-reactivity between the various membrane fractions. It is proposed that the development of membrane-specific autoantibodies may provide an immunological marker useful in the differential characterization of various subcellular membranes.

1104 THE EFFECT OF A CHEMICALLY DEFINED DIET ON THE FAECAL FLORA AND FAECAL STEROID CONCENTRATION. *(E.)* Crowther, J. S.; Drasar, B. S.; Goddard, P.; Hill, M. J.; Johnson, K. (St. Mary's Hosp., London, England). *Gut* 14(10):790-793, 1973.

Healthy males (3) consumed a liquid diet containing no fiber and virtually no fat for 10 days. The effect of this diet on the bacterial flora and the steroid composition of the feces was monitored. The change from the normal mixed diet to the liquid one resulted in a marked reduction in weight of feces passed, e.g., in one subject the weight dropped from 278 to 85 g at the end of the 10 day period. Counts of enterococci fell considerably during the 10 days and returned to their former levels on resumption of a normal diet. In 2 subjects the counts of viridans streptococci also fell. The numbers of enterobacteria increased. Counts of all other organisms were unchanged. Acid and neutral steroid concentrations in the feces of all 3 subjects fell to a mean value of 2.0 and 1.9 mg/g dry weight, resp. This was accompanied by a decrease in the degree of degradation of the neutral steroids. During the control period before the diet started, 55-75% of the total neutral steroids were in the form of coprostanol and coprostanone. By the end of the 10 day diet these metabolites accounted for only 4-10% of the total in 2 subjects and for 40% of the third. The percentage of neutral steroids in the form of cholesterol metabolites correlated well with the number of enterococci/g feces. The reduction of cholesterol to coprostanol by pure cultures of intestinal bacteria was assayed. None of the aerobic organisms performed this nuclear hydrogenation. Thus, the neutral steroids of people living on a liquid diet are virtually unmetabolized by the gut bacteria, even though the transit time in these people is remarkably long.

1105 EFFECTS OF AN ELEMENTAL DIET ON HUMAN FECAL FLORA. *(E.)* Bounous, G.; Devroede, G. J. (Gastroenterol. Res. Unit, Univ. Sherbrooke, Canada). *Gastroenterology* 66(2):210-214, 1974.

Fourteen healthy volunteers ate exclusively, for 12 days an elemental diet containing essentially 10 g/100 g of casein hydrolysate (two-thirds free amino acids, one-third oligopeptides), 14 g/100 ml of triglycerides (18% of which was medium chain triglycerides), and 67 g/100 g of disaccharides (one-half in the form of sucrose). The diet produced a decrease in stool frequency: 0.5 stools/24 hr compared with an average of 1.3/24 hr while on normal food. The average weight of stools during the 12 days on diet was 96.2 g, compared with 114.3 g while on normal food. The average counts of total anaerobes, aerobes, and coliforms per gram of diet stool were not significantly different from the corresponding values in control stools. However, there was a significant decrease in the number of enterococci. It is not possible, because of the design of this study, to determine whether the decrease in the number of enterococci is due to the liquid nonresidue, or the elemental character of the diet, or the type of statistical analysis.

1106 ISOLATION OF C4-SYNTHESIZING CELLS FROM GUINEA-PIG LIVER BY FICOLL DENSITY GRADIENT CENTRIFUGATION. *(E.)* Ilgen, C. L.; Burkholder, P. M. (Dept. Pathol., Univ. Wisconsin, Madison). *Immunology* 26(1):197-203, 1974.

Cells which synthesize the fourth component of complement have been isolated from male albino guinea-pig liver through rate zonal density gradient centrifugation of suspensions of liver cells on continuous density gradients (2 to 15%) of Ficoll. This procedure separates non-parenchymal cells from parenchymal cells on the basis of size. Cells which synthesized C4 were identified as low density, non-parenchymal cells which comprised only a small pro-

ortion of the cells added to the gradient. Phago-
ytic cells were restricted to the same portion of
he gradient as cells which synthesized C4, and
here is evidence that cells which synthesize C4
re also phagocytic. Since phagocytic activity was
ccasionally evident in cells observed in the cen-
ers of plaques, the results obtained in this invesi-
igation further support the concept that C4 syn-
hesis in the liver occurs primarily if not ex-
lusively in a reticuloendothelial cell, the Kupffer
ell.

107 PORCINE INTESTINAL CALCIUM-BINDING PROTEIN. MOLECULAR PROPERTIES AND THE EFFECT OF INDING CALCIUM IONS.

(E.) Dorrington, K. J.;
ui, A.; Hofmann, T. (Dept. Biochem., Univ. Toronto,
anada). *J. Biol. Chem.* 249(1):199-204, 1974.

calcium-binding protein from porcine intestinal
ucosa was characterized. Chromatography on
ephadex G-75 suggested a molecular weight around
2,000. Electrophoresis in sodium dodecyl sulfate-
rea-polyacrylamide gel indicated a value in the
rea cf 7000. Sedimentation equilibrium analyses
ave evidence for aggregation, with the monomeric
orm having a molecular weight between 7000 and
00. The amino acid composition, which requires a
nimum molecular weight of 9000, is: Lys_{11-12},
g_1, Asp_7, Thr_1, Ser_{6-7}, Glu_{17}, Gly_4, Ala_5, Val_3,
e_3, Leu_{10}, Tyr_1, Phe_5. No histidine, half-cystine,
thionine, or tryptophan were found. No free term-
al amino group was detected, but digestion with
nicillocarboxypeptidases S1 and S2 indicated the
OH-terminal sequence: ••••(Gly,Thr,Asp)Ala-Ile-
l(Phe,Ser)Leu-Lys-GlnOH. The circular dichroism
ectrum of the binding protein in the near ultra-
olet showed a positive peak at 276 nm with a
oulder at 282 nm characteristic of tyrosine, 2
sitive peaks at 264 nm and 257 nm, and 2 negative
aks at 268 and 261 nm characteristic of phenyl-
anine. In the far ultraviolet range 2 negative
nds at 222 nm and 207 nm were observed. Calcium
n removal decreased the tyrosine band at 276 nm to
ss than 25% its initial value, but caused no
fference in the far ultraviolet range. Ultraviolet
fference spectra between the calcium-containing and
e calcium-free protein showed peaks characteristic
tyrosine. There was no difference in sedimentation
tes. It appeared that the binding of calcium
used a local perturbance of the environment of the
ngle tyrosine residue, but no gross conformational
ange.

08 IMMUNOCHEMICAL STUDIES OF THE INTRAMOLECULAR HETEROGENEITY OF THE CARCINOEMBRYONIC TIGEN (CEA) OF THE HUMAN DIGESTIVE SYSTEM.

(E.)
ld, J. M.; Banjo, C.; Freedman, S. O.; Gold, P.
ontreal Gen. Hosp., Canada). *J. Immunol.* 111(6):
72-1879, 1973.

radioimmunoassay was devised to study the A-like
te on the carcinoembryonic antigen molecule. In
is assay anti-A antibodies were coupled to either
pharose or Sephadex beads. The following observa-
ons were made. The monosaccharide, N-acetyl-D-
lactosamine was capable of inhibiting the interaction between ^{125}I-carcinoembryonic antigen and a preparation of anti-A antibodies. A glycopeptide, (GP-1), containing the tumor-specific antigenic site of the carcinoembryonic antigen, which was obtained by the enzymatic degradation of the carcinoembryonic molecule was capable of binding to anti-A antibodies. The ratio, by weight, of this glycopeptide to N-acetyl-D-galactosamine required to achieve equivalent binding was 10^{-3} to 10^{-4} to 1. The glycopeptide has a molecular weight of about 4000 daltons, and, although it contains N-acetyl-D-glucosamine, D-mannose, D-galactose, and L-frucose, it is apparently devoid of N-acetyl-D-galactosamine. The finding of both the tumor-specific and A-like activities on the glycopeptide suggests that at least some of the carbohydrate chains of the carcinoembryonic molecule may well possess both antigenic specificities. It is suggested that these determinants may reside on a carcinoembryonic megalosaccharide similar to that proposed for the A, B, H, Le, and I blood group substances.

1109 SIMULTANEOUS ESTIMATION OF HEPATIC AND PORTAL BLOOD FLOWS BY AN INDICATOR DILUTION TECHNIQUE.

(E.) Huet, P. M.; Lavoie, P.; Viallet, A. (Hosp. St. Luc., Montreal, Canada). *J. Lab. Clin. Med.* 82(5):836-846, 1973.

Total hepatic and portal blood flows were measured in 19 dogs using indicator dilution curves from hepatic and portal veins after injection of Cr^{51}-labeled red cells into the cranial mesenteric artery. Samples were obtained simultaneously from the left branch of the portal vein and one left hepatic vein (40 experiments), and, when possible, from one right hepatic vein (27 experiments). Portal and hepatic arterial flows were estimated with two electromagnetic flowmeters during each experiment. In 40 experiments, no significant difference was found between total hepatic blood flow, portal blood flow, and portal fraction of total hepatic blood flow (portal blood flow/total hepatic blood flow) estimated simultaneously by flowmeters and indicator dilution curves. In the 27 experiments mentioned above no significant difference existed between paired total hepatic blood flows. Similar results were obtained during 9 experiments in another group of 5 dogs with ligated hepatic artery; no significant difference was found between paired total hepatic blood flow and portal blood flow estimated simultaneously by indicator dilution curves. Such findings validate the sampling from one hepatic vein for total hepatic blood flow estimation and from the left branch of the portal vein for portal blood flow estimation, demonstrating uniform mixing of the indicator in the portal vein and within intrahepatic circulation. Some high absolute flows observed using both methods resulted from the effect of radiopaque material. In 5 additional dogs, radiopaque material (50 ml) increased the cardiac blood flows. These data show the usetulness of the Stewart-Hamilton method for simultaneous estimation of total hepatic blood flow, portal blood flow, and portal fraction of total hepatic blood flow in normal dogs after injections of the indicator into the cranial mesenteric artery. Preliminary data in 11 cirrhotic subjects (9 males and 2 females, aged 36-58 yr) undergoing umbilico-portal and hepatic vein catheterization indicate that the portal fraction of total hepatic blood flow can be estimated by this method, assuming uniform mixing of the indicator in the portal vein. The portal fraction should be reliable, since the portosystemic collaterals resulting in loss of indicator occurred before the sampling sites.

1110 CHEMOTHERAPY AND ANTIBIOTIC-RESISTANCE TRANSFER BETWEEN ENTEROBACTERIA IN THE HUMAN GASTRO-INTESTINAL TRACT. *(E.)* Anderson, J. D.; Gillespie, W. A.; Richmond, M. H. (Dept. Bacteriol., Univ. Bristol, England). *J. Med. Microbiol.* 6(4):461-473, 1973.

Strains of *E. coli* were isolated from the feces of each of 5 healthy subjects (4 males and 1 female, aged 11-60 yr). These strains were genetically marked and fed to the same subject to act as a potential and easily identifiable plasmid recipient and to supplement the endogenous population of *E. coli*. By feeding a different strain of *E. coli*, also genetically marked for identification, and carrying an R factor of known properties, R-factor transfer was investigated. In the absence of antibiotic therapy, no R-factor transfer was detected. However, the R factors concerned could be transferred in laboratory studies from the potential donors to many different enteric organisms as recipients, including the genetically marked potential recipients in these experiments. Treatment of subjects with a relevant antibiotic resulted in the emergence of a number of types of resistant organism, some the potential recipients, and some not, to which transfer had occurred. This change most likely resulted from selection pressure by the antibiotics in favor of the otherwise undetectably small numbers of transcipients normally present in the gut. In 3 of the subjects, antibiotic therapy greatly increased the length of time during which ingested R factors could be detected in the feces. Loss or fragmentation of the genes of the R factors in the ingested organisms that determine antibiotic resistance was deemed unlikely. An incidental finding was that the mean number of antibiotic-resistant determinants in each type of resistant organism rose significantly with the age of the subject. At some point after the removal of selection pressure by cesation of chemotherapy, the gut will contain a mixture of approximately equal numbers of R-factor-carrying resistant strains and R-factor-less potential recipients. At this time, plasmids have the highest probability of transferring to other enterobacteria and much care must be taken in giving a second course of antibiotic therapy within some months of the original treatment.

1111 EXPERIMENTAL INTESTINAL ISCHEMIA SHOCK IN DOGS. *(E.)* Manohar, M.; Tyagi, R. P. S. (Dept. Surg., Haryana A. Univ., Hissar, India). *Am. J. Physiol.* 225(4):887-892, 1973.

Experimental intestinal ischemic shock was studied in 56 healthy adult mongrel dogs under a variety of conditions. Following restoration of blood flow to ischemic bowel after 2 hr of superior mesenteric arterial occlusion, a state of circulatory collapse developed which proved uniformly fatal. Pancreatic duct ligation, 5-6 days prior to conditioning, afforded no protection except that of abolishing tryptic enteritis. The pancreatic duct ligation probably induced tryptic pancreatitis which favored early demise of these animals. The observations on gut-sterilized dogs revealed that endotoxemia had little, if any, role in pathogenesis of the circulatory collapse state. Hypovolemia and high systemic levels of lysosomal hydrolases contributed significantly to the fate of the experimental animal. Dogs treated with immediate fluid therapy alone had prolonged survival time. Supplementing this fluid therapy with hydrocortisone premedication could protect dogs from otherwise lethal shock. The ability of epinephrine-tolerant dogs to survive the otherwise lethal shock without institution of any therapy suggests a vital role for the sympathoadrenal axis in development and progression of the circulatory collapse state after restoration of blood flow to the bowel. A unique feature in these dogs was the occurrence of intessusception of the small bowel anterior to the ileocecal junction. These findings support the view that the hypoxia after restoration of blood flow is important in causing death. Hypoxia resulted from marked hypovolemia and reduced blood flow due to hemoconcentration and elevated total peripheral resistance. This condition was probably induced and maintained by endogenous catecholamines, associated with high levels of lysosomal hydrolases in the systemic circulation, and irreversible depletion of energy-base reserves of the body.

1112 GASTRIC MUCOSAL BLOOD FLOW DURING PENTAGASTRIN- AND HISTAMINE-STIMULATED ACID SECRETION IN THE RAT. *(E.)* Main, I. H. M.; Whittle, B. J. R. (Dept. Pharmacol., Univ. London, England). *Br. J. Pharmacol.* 49(3):534-542, 1973.

Gastric mucosal blood flow was studied during pentagastrin- and histamine-stimulated acid secretion in female rats by means of a (^{14}C)-aniline clearance technique. Measurement of the mucosal blood flow in small animals cannot readily be carried out with aminopyrine since the quantities needed for accurate chemical determination require collection of larger volumes of blood and gastric juice than would be compatible with satisfactory experimental design. Aniline, however, is available as the ^{14}C isotope which allows the estimation of small amounts and is therefore potentially useful for clearance studies in the rat. There was a significant correlation between clearance and stimulated acid secretion. No significant difference was found in the relationship between clearance and acid secretion during submaximal stimulation with either pentagastrin or histamin Estimates of mucosal blood flow per unit acid secretion by (^{14}C)-aniline clearance in the rat were milar to those reported with aminopyrine clearance the dog and cat. To investigate the effect of tal aniline concentration on clearance estimates, e dose was reduced from 170 (μg/kg)/min to 1 (μg/kg)/min. Although the pattern of changes clearance is similar with the lower dose, the solute values are smaller. This implies that not l the extractable (^{14}C)-aniline in the blood is ailable for diffusion into the gastric lumen. It likely that aniline in such low concentrations bound to some constituent of blood in a manner t readily reversible during passage through the cosa. Such a possibility is supported by the exeriments which show that clearance values and the tio of clearance to acid output, when expressed terms of basal values, were not significantly fferent with either dose of aniline. Therefore, earance values obtained with very low quantities aniline do not measure absolutely but do reflect cosal blood flow.

13 TRANSPLANTATION OF CHEMICALLY INDUCED METASTATIC MUCINOUS ADENOCARCINOMAS OF THE JEJUNUM AND COLON IN RATS.

(E.) Ward, J. M.; amamoto, R. S.; Weisburger, J. H.; Benjamin, T. Iatl. Cancer Inst., Bethesda, Md.). *J. Natl. ncer Inst.* 51(6):1997-1999, 1973.

o Fischer rats given s.c. injections of 1,2-dimethylydrazine developed mucinous adenocarcinomas of the lon or jejunum which metastasized to the perioneal and pleural cavities. Portions of metaatic peritoneal tumors were transplanted into eanling rats. The latent periods after i.p. injecon were reduced from 2-3 months in the first passes to 28-35 days by the fifth passages. At necropsy these rats, tumors were found throughout the perioneal and pleural cavities. Subcutaneous transplants ew progressively and metastasized to the lungs. Histoly of transplanted tumors was similar to that of rimary tumors, with some differences. Osteoid metaasia was a feature of the jejunal transplants. though the jejunal tumor lost some of its mucusontaining cells, it still produced much extracellular ucus, which the primary tumor did not do. The colon ansplants were composed of many PAS-positive cells, t did not contain any signet ring cells suspended mucus, as did the primary tumor. Peritoneal metasses of the primary tumors had a prominent stroma, did many of the peritoneal transplants. Pleural mors in transplant rats were usually more cellular an peritoneal and s.c. tumors.

14 EFFECTS OF ACUTE RENAL FAILURE ON ILEAL EPITHELIAL CELL KINETICS: AUTORADIOGRAPHIC UDIES IN THE MOUSE.

(E.) McDermott, F. T.; lbraith, A. J.; Dalton, M. K. (Alfred Hosp., Melurne, Australia). *Gastroenterology* 66(2):235-9, 1974.

fects of acute renal failure on ileal epithelial ll kinetics were investigated by autoradiography th tritiated thymidine in BALB/c mice. Acute nal failure was produced by urinary outflow obruction and controls subjected to sham operation. 18 hr, the labeling index, mitotic index, and percentage of goblet and Paneth cells in the crypt cell population were estimated. The distribution of proliferating cells was obtained by determining the percentage of labeled cells at each cell position in the crypt cell columns. The cell cycle was analyzed by the method of percentage of labeled metaphases. A significant reduction in labeling index was found in the uremic group. The mitotic index, percentage of differentiated cells, and distribution of the proliferative zone were unaltered. In the control group, the deoxyribonucleic acid synthetic phase was 6.6 hr, and the G_2 period, plus prophase and half the metaphase duration, was 1.6 hr. The deoxyribonucleic acid synthetic phase was prolonged to 14.5 hr, and the G_2 period unaltered in the uremic group. It is concluded that acute renal failure causes an inhibition of intestinal epithelial cell proliferation in mice which is associated with prolongation of the deoxyribonucleic acid synthetic phase and the cell cycle.

1115 COMPARISON OF THE VASCULAR ESCAPE PHENOMENON IN THE INTESTINAL AND RENAL CIRCULATION WITH NEURAL AND HUMORAL INDUCTION.

(Ger.) Lutz, J.; Henrich, H. (Phsyiol. Inst., Univ. Wurzburg, Germany). *Pfluegers Arch.* 339(1):37-48, 1973.

The vascular escape phenomenon was investigated in 16 cats anesthetized with chloralose (60 mg/kg) and urethane (260 mg/kg) during simultaneous unilateral or bilateral perfusion of the superior mesenteric and renal arteries. The intestinal circulation was isolated from other circulatory systems by ligating the duodenum and colon. Vasoconstriction was induced either by stimulation of the mesenteric plexus (4-6 Hz, 0.5-1.5 millisec, 2.5-8 volts) or by additiona of norepinephrine (0.33 μg/ml) to the perfusion fluid. During electrical stimulation, escape amounted to 77.8 ± 1.7% in the intestinal circulation and to 81.1 ± 1.7% in the renal circulation, i.e. almost 3/4 of the original constriction disappeared. These 2 values are not significantly different. During norepinephrine-induced constriction, escape amounted to 53.0 ± 2.5% in the intestinal circulation and to only 23.8 ± 1.7% in the renal circulation. The escape phenomenon was observed in the intestinal circulation in 90% (n = 90) and in the renal circulation in only 67.8% (n = 118) of all experiments. These results indicate that escape is significantly more pronounced with neural than with humoral vasoconstriction and that humorally-induced vasoconstriction has a different effect on different organs.

1116 ROLE OF THE GUT MICROFLORA IN METABOLISM OF LIPIDS AND STEROLS.

DIAGNOSTIC PROCEDURES

1137 LIMITS OF THE EVOCATIVE PANCREATIC FUNCTION TEST IN THE DIAGNOSIS OF LOW-GRADE PANCREATITIS. *(E.)* van der Hoeden, R.; Wettendorff, P.; Delcourt, A. (Ixelles Hosp., Belgium). *Gut* 14(10):763-766, 1973.

Limits of the evocative pancreatic function test in the diagnosis of low-grade pancreatitis are discussed with reference to the secretory response of the pancreas and hourly urinary amylase output. Secretin was injected i.v at a dose of 1 U/kg at the same time as caerulein (Farmitalia) at a dose of 40 ng/kg was given. After injection, the biliary-pancreatic secretions were continuously aspirated for 30 minutes. When the gallbladder was emptied, 1 U/kg CCK was injected at the thirtieth minute, to provoke further enzymatic secretion from the pancreas without being affected by biliary secretions. Pancreatic secretions were then continually aspirated for a further 30 minutes. The values obtained for volume, bicarbonate output, and amylase output are markedly greater than those obtained using Boots secretin (1.5 U/kg) and pancreozymin (1.5 U/kg) or caerulein (40 ng/kg). The average of the maximum hourly urinary amylase output increased from 130 before stimulation to 354 after stimulation. By increasing the hormonal stimulation, the urinary amylase output exceeds the admitted upper normal limit when the enzyme output obtained by duodenal aspiration lies above a level of about 180/000 U/hour. This suggests that the evocative pancreatic function test loses its significance when it is carried out in conditions which render it positive in normal subjects. It can no longer differentiate patients suffering from a low-grade pancreatitis from normal subjects.

1138 "MINILAP": AN ACCURATE, RAPID AND SAFE APPROACH TO THE DIAGNOSIS OF LIVER DISEASE AND JAUNDICE. *(E.)* Wexler, M. J.; Mclean, A. P. H.; Skinner, G. B.; Maclean, L. D. (Roy. Victoria Hosp., Montreal, Canada). *Ann. Surg.* 178(6):736-744, 1973.

Minilap, a procedure for an accurate, rapid and safe approach to the diagnosis of liver disease and jaundice is presented. The patient is sedated with Diazepam and taken to the angiography suite of the Radiology Department. Once the umbilical-left portal vein membrane is opened, a black Odman radiopaque catheter with curved guide wire is inserted and manipulated under fluoroscopic control into the main portal system. The guide wire is removed and portal pressure is measured with a saline manometer. The cather is fixed in position with a ligature, and a bolus of 50-75 cc of diatrizoate meglumine is injected at a rate of 10 cc/sec. Serial films are exposed with a Picker-Amplatz rapid film changer set for one film per sec for 10 sec and one every 2 sec for an additional 10 sec. The catheter is then removed and the umbilical vein ligated. A 20 gauge 6 in needle is fully inserted into the right lobe of the liver from the anterior edge directed cranically and posteriorly. It is then slowly withdrawn while injecting contrast medium under fluoroscopic control. A hepatic vein is usually entered in the region of injection, and the immediate washout of dye is observed. If any abnormal displacement or delay in clearance of the dye is encountered, films are taken. The needle is further withdrawn until the bile duct system is entered. A slow injection of 30 cc of Renografin 76 is then made and sequential films exposed in anterior, and lateral projection and on cine. Following cholangiography, direct vision aspiration biopsies are performed using a 1.2 mm Menghini needle in all areas of suspicion. Five representative case histories from the initial 13 patients are presented. Minilap revealed: postnecrotic cirrhosis, severe portal hypertension, esophageal varices, hepatoma, and right hepatic venous obstruction in 1 patient; an absent left lobe, hemachromatosis, and metastic carcinoma in another patient; a tumor in the head of the pancreas in a third patient; chronic active hepatitis with micronodular cirrhosis, histogologicaly far advanced and progressive with active piecemeal necrosis in a fourth patient; and marked reversal of flow in the portal and splenic veins with a large splenorenal shunt and a shrunken liver with features of severe cirrhosis in the fifth patient. It is concluded that this technique is accurate, safe, and can save the patient prolonged hospitalization or needless exploratory laparotomy, with its attendant discomforts.

1139 EFFECTS OF ANTICHOLINERGIC AGENTS ON THE VISUALIZATION OF ESOPHAGEAL VARICES. *(Sp.)* Silvan Delgado, M. (Cantabria Sanit., Santander, Spain). *Rev. Esp. Enferm. Apar. Dig.* 41(4):467-474, 1973.

Radiological examinations of the esophagus were performed 30 min after administration of atropine sulfate (0.6 mg i.m.) on 20 patients (13 males and 7 females, mean age 38 yr) with no clinical symptoms of chronic liver disease or portal hypertension and on 26 patients (20 males and 6 females, mean age 45 yr) with clinical symptoms of chronic liver disease and portal hypertension who had no radiological evidence of esophageal varices when examined by conventional methods. Only 5 patients had a history of upper gastrointestinal bleeding. In the controls, esophageal motility and peristalsis decreased, the diameter of the esophagus increased, and gastrointestinal reflux often developed. No signs of esophageal varices were observed. Definitive radiological signs of esophageal varices were observed in 21 of the 26 patients with portal hypertension; in 1 case it was impossible to make a definitive diagnosis and in 4 cases no signs of varices were found. No troublesome complications occurred; the only side effect was xerostomia.

1140 HISTOLOGICAL FINDINGS IN LIVERS OF CLINICALLY NORMAL CARRIERS OF AUSTRALIA ANTIGEN (HB Ag). *(Ger.)* Klinge, O.; Kaboth, U.; Winckler, K. (Pathol. Inst., Univ. Wurzburg, Germany). *Virchows Arch.* [*Pathol. Anat.*] 361(4):359-368, 1973.

Histological examinations were made on 79 punch biopsies from the livers of 58 clinically normal carriers of Australia antigen (HB Ag) (55 men and 3 women, aged 20-30 yr) with normal serum transaminase activities and no history of hepatitis. All

f these subjects remained HB Ag-positive during
he entire follow-up period. The liver parenchyma
as normal or almost normal in 21 cases and showed
vidence of mild portal fibrosis in 2. Changes
haracteristic of cytotoxic liver damage were present
n 41 biopsies: 18 showed hypertrophy of the smooth
nodplasmic reticulum, 19 contained fat deposits
including 1 case of alcoholic cirrhosis), and chol-
stasis was present in 4. Necrosis was present in
biopsies and was associated with mesenchymal and
ortal reactions of varying degrees of severity in
ll but one case. Only 6 biopsies (8.6%) showed
vidence of chronic persistent hepatitis. Follow-up
iopsies, performed on 18 of these HB Ag carriers,
evealed that the lesions became more severe in 4
ases, decreased in severity in 4 cases, and remained
he same in 3. Persistent hepatitis developed in 3
f the 4 subjects with hepatic necrosis who were
ollowed. These findings confirm previous reports
hat most clinically normal HB Ag carriers have asso-
iated liver damage. However, without histological
xamination of the liver there is no justification
or establishing a diagnosis of subclinical hepatitis
olely on the basis of the test for HB Ag.

41 TRANSJUGULAR LIVER BIOPSY AND CHOLANGIO-
GRAPHY. *(E.)* Rosch, J.; Lakin, P.;
ntonovie, R.; Dotter, C. T. (Dept. Diagn. Radiol.,
Jniv. Oregon Med. Sch., Portland). *Fortschr. Geb.
ontgenstr. Nuklearmed.* 119(6):653-661, 1973.

e percutaneous transjugular approach to liver
iopsy and cholangiography eliminating the necessity
or traversing the peritoneal cavity and puncturing
e liver capsule, was used in 61 patients. Both
iopsy and cholangiography were done in 36 patients,
ver biopsy alone in 8 patients, and cholangio-
raphy alone in 17 patients. Diagnostic biopsy
ecimens were obtained in 39 patients (89%). Cholan-
iography succeeded in 29 of 31 patients (93%) with
larged intrahepatic ducts. There were no major
mplications. Advantages and disadvantages of this
proach in comparison to the standard transperi-
neal techniques are discussed. The transjugular
ute offers a feasible, safe and effective approach
r liver biopsy and cholangiography. Safety is its
in advantage over the standard techniques. It is
nsidered complementary to the standard transperi-
neal route for liver biopsy. The transjugular
ute is of particular value in the presence of
agulopathy, high-grade obstructive jaundice, or
jor ascites. For cholangiography, it is considered
primary approach, preferable to the standard trans-
ritoneal technique. Acute cholangitis is the prin-
pal contraindication of this approach.

42 CELL KINETICS IN FLAT (AVILLOUS) MUCOSA
OF THE HUMAN SMALL INTESTINE. *(E.)*
ight, N.; Watson, A.; Morley, A.; Appleton, D.;
rks, J. (Dept. Pathol., Univ. Newcastle upon Tyne,
gland). *Gut* 14(9):701-710, 1973.

new method for the analysis of small-intestinal
ypt-cell kinetics using routine peroral diagnostic
opsies is described. Untreated patients with
ildhood and adult celiac disease and adults with

the gluten-sensitive enteropathy of dermatitis herpetiformis were studied (62 in all), together with groups of 75 adult and 10 childhood controls. In the classical flat avillous mucosae the increase in crypt size was three-dimensional. The number of proliferating cells per crypt was markedly increased, and an even greater rise in the crypt-cell production rate was demonstrated. A significant increase in the mitotic index was also confirmed in the avillous mucosae. It is suggested that the characteristic crypt morphology in gluten-sensitive enteropathy can be explained as an adjustment to accommodate the expanded mass of proliferating and maturing cells necessary to support the augmented cell production rate. This could be a response to a pathologically rapid loss of cells from the mucosal surface.

1143 EXFOLIATIVE CYTOLOGY OF THE BILIARY TRACT WITH THE USE OF SALINE IRRIGATION UNDER CHOLEDOCHOSCOPIC CONTROL. *(E.)* Nishimura, A.; Den, N.; Sato, H.; Takeda, B. (Chiba Univ. Sch. Med., Japan). *Ann. Surg.* 178(5):594-599, 1973.

Cytological examination of the sediment obtained by collecting the irrigation fluid during the fiberoptic choledochoscopy has been performed in 25 cases of biliary tract disease and appears to be a valuable diagnostic measure for tumors in the biliary tract. Exfoliative biliary cytology is emphasized as a routine procedure, accompanying roentgenologic and endoscopic examination. Eighteen of the 25 patients had benign disease including 9 with choledocholithiasis and 8 with cholecysto-choledocholithiasis and 1 with a pancreatic cyst, none showed malignancy except 1 which was classified as Pap. Cl. III. The remaining 7 malignant cases included 1 of carcinoma of the gallbladder, 2 of the choledochus, 3 of the papilla and 1 of submucosal invasion to the choledochal wall originating from carcinoma of the head of the pancreas. These demonstrated to be malignant by exfoliative cytology with the exception of 2 cases; the one was classified as Pap. Cl. II in the case of submucosal invasion, the other as Pap. Cl. III. The latter had carcinoma of the head of the pancreas. The former false negative result was due to the minimal ulceration found on the choledochal wall where the carcinoma had spread chiefly submucosally, the latter may suggest a limitation of the cytological technic. Morphology of malignant cells in the biliary tract is characterized by prominent nucleus, enlargement of nucleus and some nuclear atypia.

1144 THE FALSE-POSITIVE PANCREAS SCAN: DOES IT REFLECT "LOW-NORMAL" PANCREATIC FUNCTION? *(E.)* Agnew, J. E.; Youngs, G. R.; Lydford, R.; Levin, G. E.; Bouchier, I. A. D. (Roy. Free Hosp., London, England). *J. Nucl. Med.* 15(2):90-93, 1974.

The mean trypsin level in 7 normal patients with abnormal pancreas scans was compared with the mean level in 16 normal patients with normal scans. A careful followup of all 23 for at least 1 yr from the time of scanning revealed no radiological or biochemical evidence of pancreatic disease. Six of the 23 patients had laparotomies at which time the pancreas appeared to be normal; 3 of these had carcinoma of the hepatic or bile ducts, 1 had cholelithiasis, 1 had irritable bowel syndrome, and 1 had abdominal pain of unknown cause. Of the 17 patients in whom laparotomy was not performed, 13 had abdominal pain of unknown cause, 2 had stones in the common bile duct, 1 had a gastric ulcer, and 1 had irritable bowel syndrome. Each of 3 observers viewed the 3 scans from each patient and then reported whether he considered the pancreas to be normal or abnormal. Seven patients were judged to have abnormal scans. Five of these had a trypsin level of 42 μM/ml/min or lower while the other 2 had levels of greater than 76 μM/ml/min. Sixteen patients had normal pancreas scans. The trypsin levels in these lay within the range 36-76 μM/ml/min. The difference between the mean trypsin level in the normal scan group and that in the abnormal scan group is not statistically significant. However, the results suggest that some patients with a false-positive pancreatic scan may have duodenal tryptic activities at the lower end of the normal range.

1145 GASTRIC EMPTYING OF LIQUIDS IN MAN. QUANTIFICATION BY DUODENAL RECOVERY MARKER.

(E.) Meeroff, J. C.; Go, V. L. W.; Phillips, S. F. (Mayo Grad. Sch. Med., Rochester, Minnesota). *Mayo Clin. Proc.* 48(10):728-732, 1973.

The duodenal perfusion technique was employed as a means of quantifying gastric emptying in 4 healthy male volunteers, between 22 and 28 yr of age. The arrival in the duodenum of a marker given in a test meal was compared with the amount of marker remaining in the stomach after varying intervals of time. The test meal was an isotonic saline solution containing 100 mg of phenolsulfonphthalein (PSP) per liter. The duodenal perfusate was an isotonic saline solution with 5 g/liter of polyethylene glycol 400 (PEG) as a recovery marker. Total recovery of PSP (the amount recovered from the stomach plus that recovered from the duodenum) was 97.6% of the amount in the meal. There was excellent agreement between the 2 means of assessing gastric emptying (total meal marker minus residual gastric marker and duodenal recovery of gastric marker). In addition, half-times, calculated from gastric recovery and duodenal arrival of the marker, also agreed closely. It is concluded that the duodenal perfusion technique has the following advantages over previous methods: kinetics of gastric emptying can be ascertained from one test meal; the need for gastric aspiration can be obviated; duodenal control of gastric emptying can be studied more directly; and secretion, absorption, and transit can be studied simultaneously.

1146 THE VALUE OF SERUM CATALASE ACTIVITY DETERMINATIONS IN ACUTE PANCREATITIS.

(E.) Meszaros, I.; Goth, L.; Vattay, G. (Munic. Hosp., Sumeg, Hungary). *Am. J. Dig. Dis.* 18(12):1035-1041, 1973.

The values of serum catalase and serum amylase activity determinations in acute pancreatitis are presented. A significant elevation of serum catalase activity was observed in 26 of 28 patients with acute pancreatitis and in 9 of 32 patients with acute cholecystitis. Serum amylase activity in the same groups was significantly elevated in 22 and in 2 cases, respectively. Serum amylase remained elevated for 1 to 3 days, while catalase remained elevated for 10 to 14 days. It is concluded that the measurement of serum catalase activity is complementary to the determination of serum amylase in the diagnosis of acute pancreatitis.

1147 TREHALOSE TOLERANCE TEST. ITS VALUE AS A TEST FOR MALABSORPTION.

(E.) Bergoz, R.; Bolte, J. P.; Meyer zum Bueschenfelde, K.-H. (Cantonal Hosp., Geneva, Switzerland). *Scand. J. Gastroenterol.* 8(7):657-663, 1973.

The value of the trehalose tolerance test as a test for malabsorption is presented. Trehalose is a disaccharide hydrolyzed to glucose by the intestinal brush border enzyme trehalase. A trehalose absorption ratio is defined by the comparison of trehalose and glucose tolerance tests. Normal values (> 0.30) have been established with 50 control patients. The following intestinal disorders were diagnosed in 51 patients: pancreatic steatorrhea (9 cases), idiopathic sprue with dramatic response to gluten-free diet (8 cases), Crohn's disease (14 cases), ulcerative colitis (7 cases), pernicious anemia (4 cases), Whipple's disease (1 case), lymphoma of the small intestine (2 cases), diffuse amyloidosis of the gut (1 case), primary lactase deficiency (5 cases), and bacterial overgrowth in the small intestines (4 patients). An abnormal trehalose absorption ratio (< 0.26) is strongly associated with the presence of malabsorption of intestinal origin. A normalization of this ratio is observed early after treatment of the underlying disease. This test seems to be very sensitive and remains valid when the d-xylose elimination test cannot be used.

1148 SERUM CARCINOEMBRYONIC ANTIGEN IN CLINICAL DISORDERS.

(E.) Booth, S. N.; King, J. P. G.; Leonard, J. C.; Dykes, P. W. (Med. Sch., Univ. Birmingham, England). *Gut* 14(10):794-799, 1973.

Carcinoembryonic antigen (CEA) levels have been measured in the serum of 490 patients and 93 normal controls using the double antibody radioimmunoassay technique. Levels were elevated in 71% of patients with carcinomata of the gastrointestinal tract including tumors of the colon/rectum, stomach, pancreas, and gallbladder, and in 42% with bronchus, breast, cervix/uterus, bladder, and prostate types of malignancy. In patients with non-neoplastic disease of the gastrointestinal tract and liver, elevated levels were found in 14 and 66% respectively. In general the CEA level tends to be higher in cancer patients with hematogenous dissemination. Following complete surgical removal of a tumor, levels fall to normal within 14 days in the majority of patients. Of 33 patients studied during follow up, elevated levels were found in 12, 10 of whom had evidence of recurrence. CEA assay could become a diagnostic tool and could also be of value in the progressive study of patients with pre-malignant or treated malignant conditions.

149 THE SIGNIFICANCE OF AUSTRALIA-ANTIBODY IN BLOOD DONORS: STUDY OF LIVER HISTOLOGY IN DONORS AND POST-TRANSFUSION HEPATITIS IN RECI-PIENTS.

(E.) Reinicke, V.; Poulsen, H.; Banke,).; Dybkjaer, E. (Copenhagen County Hosp., Denmark). *cta Pathol. Microbiol. Scand. (B)* 81(6):753-756, 973.

ystematic screening by immuno-osmophoresis of 7500 onsecutively registered Danish voluntary blood onors revealed 22 with Australia (Au)-antibody. one of these persons had a previous history of epatitis and only 3 had ever received a blood ransfusion. In 21 donors, the antibody persisted uring the entire period of investigation (34-38 onths). Liver biopsies were performed in all 22 onors. No changes such as those seen in viral epatitis or sequelae after viral hepatitis, i.e. ibrosis or cirrhosis, were found in any of the iopsies. Stimulation of Au-antibody production in he present series of donors might have been caused y cellular antigens showing cross-immunity with u-antigen and released by mechanisms other than iral hepatitis. A retrospective study of 12 reci-ients of blood transfusions from the donors with u-antibody revealed no posttransfusion hepatitis, nd in no case could Au-antigen or Au-antibody be emonstrated.

150 DISCRIMINATIVE INTEREST OF THE STUDY OF BASAL ACID SECRETION AND PEPSIN ACID COR-ELATION IN ZOLLINGER-ELLISON SYNDROME AND PEPTIC LCER.

(E.) Bernades, P.; Mignon, M.; Bensalem, .; Dubrasquet, M.; Bader, J. P.; Bonfils, S. Bichat Hosp., Paris, France). *Digestion* 9(1):1-7, 973.

arious criteria based upon study of basal acid and epsin gastric secretion are proposed to facilitate e diagnosis of Zollinger-Ellison (ZE) syndrome ave been analyzed on 599 gastric secretory studies subjects who had undergone no gastric surgery. is population included 20 ZE syndromes and 495 odenal ulcers (DU). Neither an acid concentration 100 mEq/l nor an acid output >15 mEq/h is suf-iciently discriminatory for the diagnosis of ZE ndrome when taken alone because they were found 8.2 and 6% of DU, respectively. However, the sociation of these two criteria in the same cretory study strongly increases the suspicion of is diagnosis because it was found in 60% of ZE ndrome cases and in only 2.8% of DU. A valuable dification of those criteria taken alone is the esence of a basal acid output >18 mEq/h. In the esent series, however, the most interesting criterion s proved to be pepsin/acid correlation (K 25) ual to or lower than 35. In any case, a low pepsin/ id correlation improves the suspicion of the diag-sis. The most characteristic secretory status the ZE syndrome consists of an association of a sal acid output >18mEq/h, a basal acid concen-ation >100 mEq/l and a K 25 <35 which is found 55% of ZE syndrome cases and in only 0.6% of DU without pyloric stenosis. These criteria have to be considered as a means of selection of patients in whom radioimmunoassay of serum gastrin is needed.

1151 ANGIOGRAPHY IN INTESTINAL CARCINOID.

(E.) Bjorn-Hansen, R.; Aakhus, T. (Rikshosp., Oslo, Norway). *Acta Radiol. [Diagn.] (Stockh.)* 14(6):721-728, 1973.

Case reports of 4 patients subjected to angiography for intestinal carcinoid are presented. The first case was a 65-year-old man. Angiography of the superior mesenteric artery disclosed an irregular caliber of the terminal branches of the ileocolic artery in the region of the cecum as well as of the ileal branch supplying the terminal ileum. Accumulation of contrast medium in the tumor was evident in the parenchymal phase. The angiography also revealed metastases in the liver and at operation a neoplasm in the terminal ielum was involving the cecum in accordance with the angiographic findings. Angiography of the superior mesenteric artery of the second case, a 47-yr-old woman, disclosed considerable narrowing of the lower part of this artery as well as of the ileocolic artery. Angiography of the celiac artery revealed expansive lesions in the right hepatic lobe with circumferential displacement of the arteries around them. A marked accumulation of contrast medium appeared in the tumors in the parenchymal phase. Angiography of the superior mesenteric artery of the third case, a 49-year-old female, revealed considerable irregularity of caliber and course of the superior mesenteric and ileocolic arteries distally. Operation revealed a tumor in the ileum one meter proximal to the ileocecal valve and spreading into the mesentery and lymph nodes. Angiography of the superior mesenteric artery of the fourth case, a 58-year-old female, demonstrated markedly irregular narrowing of its lower part. The artery was wide and tortuous and gave off radiating branches. Subsequent urine analysis disclosed an increased level of 5-hydroxyindoleacetic acid.

1152 ^{123}I-IODO-BROMSULPHALEIN AS A LIVER AND BILIARY SCANNING AGENT.

(E.) Goris, M. L. (Donner Lab., Univ. California, Berkeley). *J. Nucl. Med.* 14(11):820-825, 1973.

The way in which ^{123}I-iodo-bromsulphalein (^{123}I-BSP) potentially combines the advantages of ^{131}I-rose bengal (RB) and ^{99m}Tc-labelled colloids in liver function and morphine evaluation is discussed. The labeled tracer, ^{125}I-BSP, was injected i.v. into male Swiss mice weighing between 27 to 34 g. Blood samples were taken over an interval of 15 min. The total amount of BSP and its iodinated derivative, ^{125}I-BSP, injected was approximately 0.2 mg (7 mg/kg). *In vivo* stability was tested by comparing the thyroidal uptake 1 hr after injection, to the thyroidal uptake of Na^{131}I in mice who were kept on an iodine-free diet for 8 days. It was estimated that not more than 1% of the injected activity was free iodide during the course of the experiments. The extraction efficiency was higher for ^{125}I-BSP but so was the extravascular volume. Early, the computed fraction taken up by the liver was larger for BSP. From the mice experiments, it was concluded that a significant improvement over ^{131}I-RB was expected beyond those due to the physical characteristics of ^{125}I. Iodine-^{123}-BSP was injected i.v. in Beagle dogs (10 kg), and the distribution of the tracer followed with an Anger camera. The activity ranged from 0.15 to 1.5 mCi and the total amount of BSP and ^{123}I-BSP from 4 to 40 mg. It is concluded that inasmuch as ^{123}I-BSP behaves in a manner similar to ^{131}I-RB, it will furnish the same type of information otherwise not available from colloidal scanning agents. Since the isotope can be given in higher doses and is compatible with the Anger camera, pictorial information approaching the quality expected of ^{99m}Tc agent can be gained.

1153 SOLITARY ANGIODYSPLASTIC LESIONS IN THE ILEOCAECAL REGION DIAGNOSED BY ANGIOGRAPHY.

(E.) Whitehouse, G. H. (Dept. Radiodiagn., Univ. Liverpool, England). *Gut* 14(12):977-982, 1973.

Single angiodysplasias were demonstrated by preoperative angiography in 4 patients. In 2 cases, the lesions were in the terminal ileum; they were situated just above the cecum in the other 2 cases. In 3 patients, contrast medium was extravasated into the bowel lumen. Histological verification was obtained in 3 instances. In 3 cases, the superior mesenteric artery was selectively catheterized by a green Kifa catheter which was introduced from the femoral artery by the Seldinger technique. In the fourth case, 35 ml Urografin 60% was injected through a straight catheter whose tip was situated in the lumen of the abdominal aorta at the level of the lower part of the twelfth thoracic vertebral body. For the first case, a 65-yr-old male, a right hemicolectomy with removal of the terminal portion of ileum was performed. Histology showed an area of dilated abnormal arterial vessels in the ileum, with an adjacent irregular collagenous mass containing irregularly arranged bundles of smooth muscle and small capillaries, the features being those of an angiodysplasia. For the second case, a 62-yr-old male, a right hemicolectomy with removal of 6 cm of terminal ileum was performed because of the evidence of angiodysplasia found on angiography. The third case, a 37-yr-old male had a segment of ileum corresponding to the angiographic abnormality removed. The fourth patient, a 57-yr-old female underwent a hemicolectomy. There was a blood-filled submucosal space 5 cm distal to the ileocaecal valve, but no site of mucosal ulceration was present. It is concluded that the technique of selective angiography is safe in experienced hands, and the slight morbidity and mortality associated with selective arteriography must be offset against the increased chance of successful localization of the bleeding site at subsequent laparotomy and a shorter operating time.

1154 DISSECTING MICROSCOPY OF THE RECTAL MUCOSA IN HEALTH AND DISEASE. *(E.)*

Bank, S.; Novis, B. H.; Burns, D. G.; Marks, I. N. (Groote Schuur Hosp., Cape Town, South Africa). *Dis. Colon Rectum* 16(6):459-467, 1973.

The dissecting microscope was used to visualize the smaller blood vessels (microvasculature) of the rectal mucosa. Using a direct square-basket Chevalier Jackson biopsy forceps, 157 consecutive rectal biopsies were taken through the sigmoidoscope between 5 and 10 cm from the anal margin. Normal dissecting-microscopy findings were assessed from the biopsy specimens of 26 patients free of colorectal disease or diarrhea. Normal rectal mucosa has a regular honeycomb appearance. Deviations from the normal dissecting-microscopic appearance were assed primarily from 69 biopsy specimens obtained from patients with known ulcerative colitis. The clearly recognizable abnormalities were confined largely to the vascular border of the mucosal units and could be graded according to the severity of the vascular disturbance from 0 (normal) to 4 (destruction of the honeycomb pattern). Sigmoidoscopy disclosed abnormalities ranging from erythema through severe ulceration and bleeding in 60 of the 69 patients with proven ulcerative colitis. Severe sigmoidoscopic changes were associated with loss of architecture or completely disorganized (Grade 3 or 4) dissecting microscopic appearances in the majority of cases. Sigmoidoscopically, moderate colitis was associated with all grades of dissecting-microscopic vascular abnormality, but the latter was often more disturbed than the sigmoidoscopic findings suggested. Four biopsies taken from areas of ulceration with amebic colitis showed dissecting-microscopic changes similar to those found in ulcerative colitis. Of 8 specimens taken from abnormal granular mucosa in 4 patients with rectal Crohn's disease, 5 had normal regular patterns and 3 had only minimal changes. Three biopsy specimens taken from the edge of the carcinoma showed a completely disorganized vascular pattern with vessel formation and large tortuous vessels. Of 6 specimens from patients with mucosal polyps, 5 had normal dissecting-microscopic appearances and one, minimal vessel widening. There was generally good agreement between the vascular arrangements seen on dissecting microscopy and the degree of histologic change in 62 biopsies taken from patients with ulcerative colitis. It is concluded that the dissecting microscope is useful adjunct to sigmoidoscopy and provides some additional insight into mucosal appearances through the sigmoidscope.

1155 A NEW TECHNIQUE FOR EXAMINING INTESTINAL BIOPSIES. *(E.)*

Chapman, B. L.; Henry, K.; Paice, F.; Steward, J. S.; Coghill, N. F. (West Middlesex Hosp., Isleworth, England). *Gut* 14(11):905-909, 1973.

A new technique for examining intestinal biopsies is described. Proximal jejunal biopsies were obtained during the routine investigation of patients suspected of having conditions liable to affect the small intestine, including adult celiac disease and dermatitis herpetiformis. The specimens were fixed in gluteraldehyde buffered with sodium cacodylate. They were subsequently washed with sucrose-cacodylate buffer and then stained with hematoxylin and eosin (H and E), the periodic acid Schiff sequence, and hematoxylin Van Giesen. To measure the total cross-sectional areas occupied by the surface and by the crypt epithelium, a modification of the technique of television image analysis was used. A black-and-white television camera scans the object to be

xamined and converts up to 7 shades of grey into 7
olors which are displayed on a television monitor.
he colors are related to the light intensity at the
espective parts of the object. An analog computer
rocesses the television signals and the results are
isplayed in numerical form. One of the measurements
arried out by the instrument is the total area
ccupied by a given color regardless of its shape,
istribution, or number of parts. The surface cells
nd the crypt cells were put on separate drawings.
he H-and-E-stained sections of each biopsy were
rojected with a standard microprojector. The
pithelium was outlined on paper with a fine felt-
ipped pen. The junctions between surface and crypt
pithelium were arbitrarily taken to be at the bases
f the villi when those were present, and at the
rypt mouths when villi were absent. The television
mage analyser was used to measure the total area
ccupied by the black ink on each drawing. Twelve
ontrol and 12 celiac mucosae were examined. For
he control mucosae, the mean area ratio of the sur-
ace epithelial area to the crypt epithelial area
as 2.27. For the flat celiac mucosae, the mean
rea ratio was only 0.24. It is concluded that this
echnique is of value as a research technique and for
he measurement of minor changes in the mucosa such
s those occurring during treatment of celiac disease
ith a gluten-free diet.

156 THE LUNDH TEST IN THE DIAGNOSIS OF PANCREATIC DISEASE: A REVIEW OF FIVE
EARS' EXPERIENCE. *(E.)* Mottaleb, A.; Kapp, F.;
oguera, E. C. A.; Kellock, T. D.; Wiggins, H. S.;
aller, S. L.(Central Middlesex Hosp., London,
ngland). *Gut* 14(11):835-841, 1973.

n analysis of 523 Lundh tests performed on 492
atients for the diagnosis of pancreatic disease
ver a 5-yr period is presented. Nonpancreatic
atients were those in whom ultimately no evidence
f pancreatic disease was found. Pancreatic disease
as considered to be proven if there was: 1) X-ray
idence of pancreatic calcification, 2) operative
necropsy findings of pancreatic disease, or 3)
the serum amylase was higher than 1100 IU/l dur-
g an attack of pain. There were 235 patients
ith no evidence of exocrine pancreatic disease,
re not diabetic, and had not had gastric surgery:
ese form the control group. Of the 77 patients
ith proven pancreatic disease and biliary tract
rcinoma (including acute and relapsing acute
ncreatitis), 46 (60%) had an abnormal mean tryptic
tivity; if, however, only those patients with
ronic pancreatitis or carcinoma of the pancreas
re considered, the proportion with a mean tryptic
tivity of 6 or less rose to 71%. Eight patients
th biliary tract carcinoma and 14 of 23 patients
th carcinoma of the head of the pancreas presented
th jaundice. Of those with pancreatic carcinoma,
d jaundice, 71% had an abnormal mean tryptic
tivity. Sixty-five per cent of patients with
undice caused by malignant lesions had no bile
the duodenal contents at any time during the
st compared with only 5% of patients with nonmalig-
nt lesions. There were only 6 false positive
sults in 523 tests and 4 were caused by faulty
sitioning of the sampling tube. It is concluded
that the Lundh test is a simple, yet accurate method for diagnosing exocrine pancreatic insufficiency in selected patients.

1157 RAPID SCREENING OF INCREASED BILE ACID DECONJUGATION AND BILE ACID MALABSORPTION BY MEANS OF THE GLYCINE-1-(^{14}C) CHOLYLGLYCINE ASSAY. *(E.)* Pedersen, L.; Arnfred, T.; Thaysen, E. H. (North Aalborg Hosp., Denmark). *Scand. J. Gastroenterol.* 8(7):665-672, 1973.

An evaluation was made of the glycine-1-(^{14}C) cholylglycine assay for rapid screening of increased bile acid deconjugation and bile acid malabsorption in 93 subjects: 19 control patients, 14 patients with various abdominal disorders probably not associated with a disturbed turnover of bile acids (Group 1); 18 patients with ulcerative or regional colitis without preliminary evidence of terminal ileopathy (Group 2); 21 patients exposed to bacterial overgrowth in the proximal gut (Group 3); 9 patients with evidence of terminal ileitis (Group 4); 7 patients with terminal ileal resections of from 40 to 60 cm of the gut; and 5 patients with obscure long-standing watery diarrhea. Fasting patients were fed a 300 ml test meal mixed with 3 g of carmine and containing 10 μCi of glycine-1-^{14}C labeled cholylglycine. The total radiation dose is approximately 125 mrad. Duplicate breath samples (air blown through a glass tube into a counting vial containing 4 ml of trapping solution) were obtained before the test meal and 2, 4, and 6 hr after ingestion. A 24-hr fecal collection was commenced with the first appearance of the carmine in stool. In the control patients, the $^{14}CO_2$ specific activities in breath ranged between 0.01 and 0.09%, whereas the 24-hr stool collections contained from 0 to 7% of the ^{14}C radioactivity administered. One patient from the first group had an abnormal ^{14}C cholylglycine assay. In 17 out of the 18 patients in the second group, the ^{14}C cholylglycine assay was negative. An increased $^{14}CO_2$ specific activity was found in 14 out of 21 patients in the third group. All of the 9 patients in the fourth group had an increased ^{14}C radioactivity in stool, whereas only 5 of them had an abnormal $^{14}CO_2$ specific activity in breath. The fecal ^{14}C radioactivity was increased distinctly in 6 out of 7 patients with resections. Out of 30 patients with chronic diarrhea, 5 had an abnormal ^{14}C cholylglycine assay. It is concluded that the assay is a reliable semiquantitative screening procedure which can be applied on an out patient basis.

1158 SERUM LIPASE ACTIVITY AFTER RETROGRADE TRANSDUODENAL PANCREATOCHOLANGIOGRAPHY. *(Ger.)* Grimmel, K.; Liehr, H.; Kasper, H.; Kulke, H. (Med. Clin. Univ. Wurzburg, Germany). *Dtsch. Med. Wochenschr.* 99(2):43-48, 1974.

Serum lipase activities were measured before, immediately after, and 24 hr after transduodenal pancreatocholangiography in 21 patients. Transient increases in serum lipase activities to more than 200 mU/ml occurred in 10 of 15 patients who underwent retrograde pancreatocholangiography; none of the

10 patients developed clinical symptoms. The increase in serum lipase activity appeared to be correlated with the extent and intensity with which the pancreatic ducts were visualized. The activity of this enzyme increased in only 1 of 4 patients in whom only the pancreatic duct and first-order accessory ducts were visualized, in 7 of 8 in whom second-to fourth-order ducts filled with contrast media, and in all 3 patients in whom the acini were visualized. Two patients developed severe cases of acute pancreatitis: in one serum lipase activities normalized rapidly after glucagon treatment, but the other failed to respond to Trasylol or glucagon and had a pancreatic pseudocyst and pus in a dilated pancreatic duct at laparotomy. Serum α-amylase activities remained normal in 9 of the 10 patients who had elevated serum lipase activities. Pathological increases occurred in 5 of 6 patients with increased serum lipase activities after injection of 100 U secretin. This test may be useful in predicting which patients will develop pancreatitis after pancreatocholangiography.

1159 ^{99m}Tc SODIUM PERTECHNETATE SCANNING OF THE ABDOMEN, A VALUABLE TOOL FOR DETECTION OF MECKEL'S DIVERTICULUM. *(E.)* Geerken, R. G.; Collin, D. B. (Walter Reed Army Med. Ctr., Washington, D.C.). *Med. Ann. D.C.* 42(11):556-557, 1973.

A case report is presented of the use of ^{99m}Tc Sodium Pertechnetate scanning of the abdomen as a valuable tool for detection of Meckel's diverticulum. A 16-year-old boy first noted mild, cramping periumbilical pain followed by passage of bloody stools. Symptoms continued for 3 days with development of weakness and dizziness and he was hospitalized. Diagnostic studies included a normal proctosigmoidoscopy, upper gastrointestinal series with small bowel follow through and barium enema. Three months later, he again noted rectal bleeding. At this time, a liver-spleen scan revealed a central defect consistent with hematoma or cyst. He underwent Gamma-camera scanning of the abdomen 30 min after intravenous injection of 100 μCi/kg of ^{99m} technetium sodium pertechnetate. The scan revealed a focus of activity in the right lower quadrant distinct from the urinary bladder, an appearance similar to previously reported examples of Meckel's diverticulum located by this technique. At laparotomy a 3.5 or 2.0 x 1.5 cm Meckel's diverticulum 90 cm proximal to the ileocecal valve was identified and removed. An incidental apendectomy was performed and the enlarged spleen removed for diagnosis. It contained a 4.5 x 6 cm epidermoid cyst. It is concluded that this relatively simple radioisotope procedure can lead to a correct preoperative diagnosis in a person with recurrent rectal bleeding, and negative proctosigmoidoscopy and barium radiography.

1160 A PATHOGNOMONIC ROENTGENOLOGIC SIGN OF REGIONAL ILEITIS (CROHN'S DISEASE). *(E.)* Welin, S.; Welin, G. (Univ. of Lund, Malmo. Sweden). *Dis. Colon Rectum* 16(6):473-478, 1973.

A roentgenographical analysis of 150 cases of surgically verified regional ileitis involving the colon and of about 200 cases of ulcerative colitis is discussed. A distinction between the 2 syndromes was almost always possible. The swollen mucosal folds with the more or less deep transverse grooves between them are clearly visible on the roentgenographs in regional ileitis. Also required for the diagnosis of regional ileitis are the transverse, narrow, and usually very distinct (though sometimes diffusely outlined) stripes of contrast medium. As a rule, they are more than 1 cm long on the roentgenograms. They are straight, while the rest of the haustra usually appear somewhat curved. The stripes could result from contrast medium situated in the deep grooves between the coarse mucosal folds, which can be seen in the operative specimens, or they may be produced by fiord-like fissures or by ulcerations. No transverse stripes have been found in the 200 surgically verified cases of ulcerative colitis. It is concluded that there is a pathognomonic roentgenologi sign of regional ileitis involving the colon, permitting differential diagnosis of this disease and ulcerative colitis.

1161 ENDOSCOPIC CHOLANGIOGRAPHY FOR BILIARY SYSTEM DIAGNOSIS. *(E.)* Vennes, J. A.; Jacobson, J. R.; Silvis, S. E. (VA Hosp., Minneapolis Minn.). *Ann. Intern. Med.* 80(1):61-64, 1974.

The results of endoscopic cholangiography for biliary system diagnosis were evaluated in 108 patients. In 70 patients, a preliminary diagnosis of extrahepatic biliary obstruction had been made and surgical management was planned. In 38 patients with presumptive primary liver disease, the question of coexisting extrahepatic obstruction could not be answered by clinical study. Endoscopic cholangiography provided necessary diagnostic information for 90 of the 108 patients (83%). Of the 108 patients, 60 proved to have extrahepatic biliary obstruction. In 3 other patients, diagnosis of tumor in the ampullary area was made endoscopically. In 13 patients, the preliminary diagnosis of obstruction of the extrahepatic duct was reversed. The site of ductal obstruction was evident before surgery in 47 patients, and in 42 of these the cholangiographic features led to a correct diagnosis of choledocholithiasis, tumor, or stricture. In 3 additional patients, the diagnosis of periampullary mass was made by cholangiography. Six of the 38 patients with primary liver disease had extrahepatic bile duct obstruction. Complications occurred in 9 patients within 36 hr after visulization of an obstructed common bile duct. Seven patients developed fever with a clinical diagnosis of cholangitis and required emergency surgical decompression. Transient respiratory depression occurred in 1 patient during precannulation sedation. Periampullary dye was observed in 1 patient, but the patient had no postcannulation complications. Asymptomatic hyperamylasuri occurred in more than 33% of the patients. It is concluded that endoscopic cholangiography is of definite clinical and economic benefit in selected patients with biliary tract disease.

1162 NONSURGICAL, PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY-DIAGNOSTIC SIGNIFICANCE IN MEDICAL PROBLEMS OF THE LIVER. *(E.)* Okuda, K.;

anikawa, K.; Emura, T.; Kuratomi, S.; Jinnouchi,
.; Urabe, K.; Sumikoshi, T.; Kanda, Y.; Fukuyama,
.; Musha, H.; Mori, H.; Shimokawa, Y.; Yakushiji,
.; Matsuura, Y. (Chiba Univ. Hosp., Japan). *Am. J.*
g. Dis. 19(1):21-36, 1974.

rcutaneous transhepatic cholangiography was car-
ied out from the right flank on 314 patients with
epatobiliary disease, using a very thin needle.
e procedure was successful in all 95 patients with
lignancies of the liver, bile duct, or pancreas;
104 of 121 patients with gallsontes; in 15 of 18
tients with other surgical diseases (cholecystitis,
enosis of the common duct, internal fistula, and
iopathic choledochus dilation; and in 54 of 80 pa-
ents with nonsurgical hepatobiliary diseases and
to minimal dilation of intrahepatic bile ducts.
the 80 nonsurgical cases, 4 had normal liver; the
hers had intrahepatic cholestasis (20), acute
patitis (11), chronic hepatitis (1), cirrhosis of
e liver (13), post-cholecystectomy syndrome (18),
olangitis (2), clonorchiasis (2), miliary liver ab-
ess (1), hepatobronchial fistula (1), insufficiency
papilla of Vater (1), and Dubin-Johnson syndrome
). The 65% success rate in visualizing intrahepatic
cts in nonsurgical patients was the result of in-
cting contrast medium instead of suctioning bile.
rcutaneous transhepatic cholangiography was of par-
cular diagnostic significance in distinguishing
trahepatic cholestasis from extrahepatic biliary
struction; it also elucidated the cause of biliary
lics and demonstrated intrahepatic stones, malfor-
tions, inflammation along the biliary tract, and
e location and extent of neoplastic invasion. It
metimes provided unexpected information, such as
unusually small bile duct system in the case of
in-Johnson syndrome. The technique may serve the
e purpose as portography and hepatic arteriography
ce these vessel systems run together with the bile
t. Complications were most frequent in patients
h malignancies and included fever, drop in blood
ssure, bile leakage, biliary peritonitis, and
gh. The only complication in the nonsurgical
up was a cough in the patient with hepatobronchial
tula.

3 VALIDITY OF TRANSHEPATIC PULP PRESSURE MEASUREMENTS.

(E.) tenHove, W.; Popovic,
B.; Howard, M. M.; Leevy, C. M. (Coll. Med. Dent.,
Jersey, Newark). *Am. J. Dig. Dis.* 19(1):15-20,
4.

reliability and validity of transhepatic pulp
ssure measurements were studied in 39 patients
h clinical evidence of liver disease, a prothrom-
time within 2 sec of normal control values, and
ormal bleeding and clotting time. Cineangio-
phy was used to document the position of the
dle, and transhepatic pressures were compared
h those obtained by wedging a catheter in the
atic vein or catheterizing the umbilical-portal
n. Transhepatic pressure was measured by a modi-
ation of the Vennes technique with the patient
ng prone. Pressure measurements produced little
comfort or residual pain. Cineangiography in 27
ients revealed 4 patterns: 1) puddling of renogra-
in the area of the tip of the needle with its
rapid dispersion through connecting outflow channels in 13 patients; 2) immediate entry of renografin into a small vascular inflow or outflow conduit without puddle formation in 6 patients; 3) subcapsular extravasation of renografin with its stagnation and persistence under the capsule over a period of observation in 6 patients; and 4) entry of renografin into the biliary system in 2 patients. There was a good correlation between the wedged pressure and transhepatic pressure (r=0.96) and between transhepatic pressure and portal pressure (r=0.99) when puddle formation occurred. Transhepatic pressures were also identical to those obtained when the needle entered an inflow portal venule. When it entered an outflow hepatic venule, or the subcapsular area, the pressures were significantly lower than the pressure existing in the portal vein. Serial studies of alcoholics with active hepatic disease and elevated transhepatic pressures showed a decrease toward normal of the portal pressures with improvement of liver cell morphology. It is concluded that transhepatic pressure measurements are identical to those obtained by hepatic vein or umbilical portal vein catheterization if the needle causes puddle formation or is introduced into a portal venule and a proper external reference point and a nonoccluded needle are used.

1164 A COMPARATIVE STUDY OF FOUR METHODS FOR DETECTING GIARDIA LAMBLIA IN CHILDREN WITH DIARRHEAL DISEASE AND MALABSORPTION.

(E.) Kamath, K. R.; Murugasu, R. (Dept. Pediatr., Univ. of Malaya, Kuala Lumpur, Malaysia). *Gastroenterology* 66(1):16-21, 1974.

Four methods for detecting *Giardia lamblia*, namely examinations of stools, duodenal aspirates, intestinal biopsies, and impression smears of intestinal mucosa, were evaluated prospectively in 21 Malaysian children (aged 11 months to 5 yr) with acute or chronic diarrheal disease or with malabsorption. The parasites were detected by one or more of these methods in 12 patients. Although stool examinations were diagnostic in only 6 patients, duodenal aspirates were positive in 10. All 12 infections would have been detected by combining results of examination of stools and duodenal aspirates. Mucosal impression smears and biopsies gave the highest yield of positive tests; they were diagnostic in all 12 patients in whom parasites were detected by any of the diagnostic methods. Detection of parasites in biopsies was a tedious and time-consuming process, requiring careful scrutiny of several sections before positive identifications could be made. Evaluation of mucosal impression smears for parasites was easier and quicker than examining biopsies. Examination of mucosal impression smears for *G. lamblia* is recommended as a useful initial step in the routine evaluation of intestinal biopsies.

GASTROINTESTINAL DISEASES

ESOPHAGUS

1229 THE ABNORMAL LOWER OESOPHAGEAL SPHINCTER IN PERNICIOUS ANAEMIA. *(E.)*

Farrell, R. L.; Nebel, O. T.; McGuire, A. T.; Castell, D. O. (U.S. Naval Hosp., Philadelphia, Pa.). *Gut* 14(10):767-772, 1973.

Lower esophageal sphincter pressure was studied in 9 pernicious anemia patients and 15 controls using an infused open-tipped system. Resting sphincter pressure was significantly ($P < 0.01$) lower in the pernicious anemia patients. After gastric acidification with 0.1 N HCl pressure fell significantly ($P < 0.01$) in both groups. Following subsequent alkalinization, lower esophageal sphincter pressure for controls rose significantly ($P < 0.001$). For pernicious anemia patients the pressure after alkali was not greater than resting levels. Graded intravenous doses of pentagastrin in controls resulted in a peak pressure change of 38.5 ± 4.9 mm Hg after the 0.8 μg/kg dose. For patients the peak pressure change was only 13.0 ± 5.2 mm Hg and occurred after 0.4 μg/kg. Cholinergic stimulation with edrophonium (10 mg) produced a peak pressure change of 20.6 ± 2.6 mm Hg in controls but only 3.5 ± 1.0 mm Hg in pernicious anemia patients ($P < 0.001$). In addition, no change in lower esophageal sphincter pressure occurred in patients after stimulation with subcutaneous betazole (1.5 mg/kg). The lower esophageal sphincter in pernicious anemia is characterized both by a lower resting pressure and decreased response to endogenous and exogenous stimuli. Thes results suggest a primary end organ defect and most likely indicate abnormal smooth muscle function in pernicious anemia. Resting sphincter pressure levels and edrophonium response in age-matched subjects indicate that these changes are not due to aging alone.

1230 CHARACTERISTICS OF LOWER ESOPHAGEAL SPHINCTER FUNCTION IN SYMPTOMATIC DIFFUSE ESOPHAGEAL SPASM. *(E.)*

DiMarino, Jr., A. J.; Cohen, S. (Univ. Pennsylvania Hosp., Philadelphia). *Gastroenterology* 66(1):1-6, 1974.

The characteristics of lower esophageal sphincter function in patients with symptomatic diffuse esophageal spasm were compared with age-matched control subjects. All patients with symptomatic spasm were diagnosed by: (1) a history of substernal chest pain and dysphagis; and (2) characteristic manometric abnormalities in peristalsis. In the patients, lower esophageal sphincter pressure was 28.2 ± 2.5 mm Hg as compared with 19.2 ± 1.3 mm Hg in control subjects. However, the pressure was normal in 18 of the 27 patients. The percentage of decrease in pressure upon swallowing was 96.2 ± 1.8% in control as compared with 80.9 ± 4.8% in all patients with spasms. However, the percentage of lower esophageal sphincter relaxation was normal, 98.4 ± 0.5%, in 17 patients. In the other 10 patients, the percentage of relaxation was 51.3 ± 5.0%. The results of this study suggested that: (1) most patients with symptomatic diffuse esophageal spasm have a normal lower esophageal sphincter pressure and normal relaxation upon swallowing; and (2) a minority of patients with spasm have impaired relaxation with or without an increased pressure.

1231 ALGINATE/ANTACID IN THE REDUCTION OF GASTRO-OESOPHAGEAL REFLUX. *(E.)*

Stanciu C.; Bennett, J. R. (Hull Roy. Infirm., England). *Lancet* (7848):109-111, 1974.

Three randomised groups of 20 patients with gastroesophageal reflux were studied using 15-hr recordings of lower esophageal pH, before and after two weeks' treatment, either with an alginate/antacid compound (Gariscon), antacids alone, or a placebo tablet. Significant reduction in the number of reflux episodes and percentage time during which the lower esophageal pH was acid was noted in the gaviscon group after treatment, whereas no significa changes occurred in the other two groups. Symptoms reported by patients during the second test were fe after gaviscon treatment than after antacid alone. Alginate seems to play the important role, for in th group treated only with the antacid part of gavisco there was no improvement in the results of reflux tests. There was also a reduction in the number of reflux episodes in patients receiving the compound. This suggests that alginate also acts as a physical barrier at the gastro-esophageal junction. The lac of significant improvement of symptoms in this stud may simply reflect the short period between the 2 assessments, and a longer clinical trial, paying attention to symptoms, is required.

1232 METABOLIC DISTURBANCE AFTER GASTRO-OESOPHAGEAL RESECTION. *(E.)*

Markkanen, T. (Dept. Med. Microbiol., Univ. of Turku, Finland) *Int. J. Vitam. Nutr. Res.* 43(4):549-554, 1973.

The transketolase activity of red cells, as an indicator of thiamine nutrition, was studied in 286 control and experimental subjects. The experimenta subjects belonged to the following groups: esophageal resection with esophago-gastric reconstruction proximal gastrectomy with esophago-antrostomy reconstruction, distal partial gastrectomy according to Billroth II, and total gastrectomy with end-to-side esophago-jejunostomy. The operations were performed for carcinoma of the esophagus or for a high gastric carcinoma, and the Billroth II recect for gastric ulcer. About 33% of the operated patie had a red cell transketolase activity lower than th of the controls, and in about 17% this activity was very strongly pathologic. These patients were considered to be affected with thiamine deficiency. The serum contents of copper, zinc, manganese and nickel after partial distal gastrectomy did not differ significantly from the corresponding control values, not even in the patients who had developed sideropenia. It is concluded that, after proximal partial gastrectomy, if transketolase activity fal arly 33% of those patients develop thiamine ficiency of varying degrees.

8 CYTOLOGY IN THE ESTIMATION OF THE SURVIVAL RATE OF PATIENTS WITH GASTRIC CANCER. TEN RS' FOLLOW-UP OF 140 CASES OF MALIGNANCIES. *(E.)* pala, K. (Central Hosp., Vaasa, Finland). *Scand. J. troenterol.* 8(6):529-531, 1973.

influence of cytological findings on the resec- n rate and subsequent survival rate in 140 patients suffering from gastric malignancies was examined in a 10-yr study in Finland. The cytological findings were graded according to Papanicolaou and were suggestive of malignancies in 82.1% of the cases with subsequently confirmed malignancies. After 5 yr, 26.6% of the patients who underwent resection (16/60) were alive; after 10 yr, the survival rate was 20% (12/60). The average 5-yr survival rate for the entire group was 11.4% (16/140); the 10-yr survival rate was 8.6% (12/140). The usefulness of cytological examinations may be demonstrated by the 5-yr survival rates, which increased in relation to the increase in the surgical rate. Thus, the 5-yr survival rate increased in the resected group from 11.8% in 1957 (when 61% of the cytologically examined patients were operated on) to 36.5% in 1959 (when 75% of the examined patients underwent surgery).

1249 DIAGNOSIS OF GASTRIC LYMPHOMA. *(Sp.)*

Velloso Jimenez, A.; de la Santa Lopez, J.; Belda Laguna, O. (Virgen del Rocio Munic. Sanit., Sevilla, Spain). *Rev. Esp. Enferm. Apar. Dig.* 41(3):375-384, 1973.

Of 7 gastric lymphomas diagnosed in a 2-yr period, 2 were limited to the stomach, 2 also involved the intestine, and 3 had become generalized. The patients consisted of 4 women and 3 men, aged 40-70 yr (mean age 58.2 yr). In 4 cases the radiological examination showed diffuse giant folds which, in 1 case, were associated with an ulcer of the greater curvature of the stomach. In the other 3 cases the tumor was localized in the antrum or fundus. Endoscopic examinations of diffuse gastric lymphomas confirmed the radiological findings and revealed the presence of small diffuse ulcers and erosions. Localized lymphomas could not be differentiated from adenocarcinomas by endoscopy. The first biopsy was positive in 5 of these 7 cases. The diagnosis was established from the third biopsy in one case and only from material removed at surgery in another.

1250 PATHOLOGY OF GASTRIC CARCINOMA IN JAPANESE POPULATIONS: COMPARISONS BETWEEN MIYAGI PREFECTURE, JAPAN, AND HAWAII.

(E.) Correa, P.; Sasano, N.; Stemmermann, G. N.; Haenszel, W. (Biometry Branch, NIH, Bethesda, Md.). *J. Natl. Cancer Inst.* 51(5):1449-1459, 1973.

The pathology and related epidemiologic aspects of gastric cancer in Japanese populations of Japan and Hawaii were studied through data and specimens from 407 cases in Miyagi prefecture, Japan, and 256 cases in Hawaii. The estimated incidence rates for diffuse carcinomas were the same in both localities, but the corresponding rates for intestinal, mixed, and other types were substantially lower in Hawaii. The slopes of the incidence curves for intestinal, mixed, and other types were similar in the subgroups considered, but the curves were displaced horizontally to the right (to older ages) in Hawaii as compared to Japan and in females as compared to males. The slope of the incidence curves for diffuse were less steep than for intestinal, mixed, and other types and did not exhibit horizontal displacement. The slopes and displacement of the type-specific incidence curves can be reconciled with the variation in sex ratios by age observed in Japan and Hawaii. An association with blood group A in the Japanese populations studied was limited to diffuse-type tumors. The different age-incidence slopes strengthen the hypothesis that diffuse type is a separate entity from the intestinal, mixed, and other types of gastric carcinoma. The association with blood group A to diffuse carcinomas suggests that the etiology of these tumors may be more closely tied to host-related factors. The consistent slope values for types other than diffuse in Japan and Hawaii suggest that the forces contributing to the rise in incidence with age are similar once some critical age has been reached. Attainment of a certain extension, intensity, or atypia in the metaplastic process may lead into the subsequent induction of gastric carcinoma. This would explain why moving to a lower-risk environment does not suppress the development of gastric carcinoma among migrants from high-risk areas.

1251 CYTOLOGY OF THE GASTRIC MUCOSA IN THE DEVELOPMENT OF CHRONIC GASTRITIS. *(E.)*

Cheli, R.; Carli, C.; Ciancamerla, G. (St. Martino Hosp., Genoa, Italy). *Am. J. Dig. Dis.* 19(2):161-166, 1974.

Gastric cytologic findings were correlated with histopathologic alterations of 131 gastric biopsies from 90 patients in various stages of chronic gastritis. The amount of cellular content in the 42 normal gastric specimens was usually moderate. In the 41 cases of superficial gastritis (inflammatory cell infiltrate limited to area of gastric pits), the gastric specimens usually contained an abundant amount of material. The inflammatory cell infiltrate consisted of neurophile granulocytes, lymphocytes, and rarely of histiocytes. The cytologic findings associated with the 8 cases of interstitial gastritis (interglandular inflammatory cell infiltrate) were similar to those in cases of superficial gastritis. The specimens in the 16 cases of preatrophic gastritis (diffuse inflammatory cell infiltrate throughout major part of the mucosa with reduction in the number of secretory glands and with beginning intestinal metaplasia) contained inflammatory cells (granulocytes, lymphocytes, plasma cells, and rarely histiocytes) and groups of mucous cells and goblet cells. In 5 cases, nuclear alterations were noted in surface mucosal cells. Inflammatory cells, particularly lymphocytes, were numerous, though not consistently present in the 18 cases of atrophic gastritis (extensive inflammatory cell infiltration throughout the entire mucosa with disappearance of gastric secretory glands and consistent presence of intestinal metaplasia). The cells from specimens of the stomach remnant with gastritis (incomplete intestinal metaplasia, 4 cases and complete intestinal metaplasia, 2 cases) usually revealed a variety of changes including those of the nuclear structure which were found in cases of atrophic gastritis. However, the gastric fragments of columnar cells with striated borders and goblet cells which resemble those of the intestine were rarely encountered. The observed cellular changes and their relationship to gastric disorders are probably based on a multitude of factors associated with inflammation, which impair cell maturation by means of hypoxic and abnormal metabolic influences.

In turn, their effect on the cells is probably favored by the resulting transformation of the mucosal structure.

1252 HISTOLOGICAL TYPES OF GASTRIC CANCER AND ITS RELATIONSHIP WITH INTESTINAL METAPLASIA.

(E.) Munoz, N.; Matko, I. (International Agency Res. Cancer, Lyon, France). *Recent Results Cancer Res.* 39:99-105, 1972.

The relationship of intestinal metaplasia to histological types of gastric cancer was studied. The histological sections from surgical specimens or biopsies of gastric cancer were classified into 3 groups: intestinal type, diffuse type, and others. The histological sections were obtained from the departments of pathology of Columbia, Mexico, Poland, and Yugoslavia. The high risk areas include Cali, Colombia; Maribor, Yugoslavia: and Gliwice, Poland. There were 434 total cases from these geographic areas. The percentage of intestinal histological types was 50.5; diffuse, 34.8; and others, 14.7. The ratio of intestinal to diffuse was 1.45. The low risk areas include: Cartagena, Columbia; Barranquilla, Columbia; Mexico City, Mexico; and Koper, Yugoslavia. There was a total of 184 cases: 37% were intestinal, 49.4% were diffuse, and 13.6% were others. The ratio of intestinal to diffuse was 0.75. The intestinal type is most frequent in men and in older age groups; the diffuse type does not show a significant difference by sex, but it is more frequent in the younger ages. Most of the reduction in gastric cancer rates during the last decades can be accounted for by a decrease in the intestinal type. A total of 2,334 blind gastric biopsies taken from 1962 to 1970 and 437 guided biopsies taken from 1966 to 1970 were reviewed for the presence of intestinal metaplasia. Twenty seven cases of gastric cancer were found mong the 376 patients with intestinal metaplasia nd one case among the 293 controls. A higher requency of gastric cancer was found among the guided biopsies. Only 3 of the 27 cases of astric cancer were diagnosed at least 1 yr after he gastric biopsy was taken. The other 24 cases hich occurred among the intestinal metaplasia atients and the one which occurred among the ontrol group, all were diagnosed at the time of he biopsy or a few months after. It is conluded that patients with intestinal metaplasia have higher risk of developing gastric cancer than ge- and sex-matched controls with biopsies negaive for intestinal metaplasia and than the general opulation.

253 MICROFLORA OF SMALL INTESTINE, INCIDENCE OF STEATORRHOEA AND INDICANURIA BEFORE ND AFTER CONVERSION OF BILLROTH II TO BILLROTH I YPE OF GASTRIC RESECTION.

(E.) Engstrom, J.; ellstrom, K.; Lundh, G.; Lonnqvist, B. (Karolnska Inst., Stockholm, Sweden). *Acta Chir. Scand.* 39(6):546-550, 1973.

ll aspirates from the efferent loop of 9 patients 2 females and 7 males, aged 46-68 yr) subjected to a Billroth II gastric resection contained more than 10^5 aerobic colonic and/or common pharyngeal microorganisms/ml. Bacterial cultures from operative specimens from the contents of the efferent loop and the liver showed positive growth in only 3 of 8 and in 1 or 7 patients, resp. After the conversion of the Billroth II to a Billroth I type gastrectomy, the total concentration of bacteria in the upper small intestine was basically unchanged, but pharyngeal species became more prevalent and were recovered from the aspirates of all subjects. When examined 2-25 months after reoperation, 4 of the 9 patients were basically free from postcibal symptoms which had been the reason for the reoperation in all cases. Following the operation, the body weight remained constant in 7 subjects while it increased in one and decreased in another. The fecal fat and urinary indican excretions decreased in 6 of 7 and in 5 of 6 patients, resp. The results of this study indicate that, to some extent, the microflora from the small intestine was related to the type of anastomosis. These results also indicate that microbiological findings in aspirates of the efferent loop do not reflect the bacterial state of the afferent loop and the liver. It appears that the malabsorption in the present Billroth II patients was due only to a small extent to the proliferation of microorganisms in the proximal part of the gastrointestinal tract.

1254 THE IMMUNOLOGICAL QUANTIFICATION OF AN ACID-STABLE CARBOXYL ESTERASE IN THE GASTRIC JUICE OF PATIENTS WITH PERNICIOUS ANEMIA AND CHRONIC ATROPHIC GASTRITIS.

(E.) Rapp, W.; Fisher, J. M.; Taylor, K. B. (Stanford Univ. Sch. Med., Calif.). *Digestion* 9(2):124-129, 1973.

The antigenic acid-stable esterase produced by the surface mucus-secreting cells of gastric mucosa has been quantified in basal and histalog-stimulated fractions of gastric juice from 23 patients and 7 controls, using the single linear immunodiffusion technique. In controls, the mean output of the esterase was 121 mg dry weight/hr during basal secretion which increased during stimulation to 571 mg/hr. In the 23 patients, all with biopsy-proven severe atrophic gastritis and 15 of whom had pernicious anemia, esterase secretion was zero in 20 and negligible in 3. Since the esterase is produced by the epithelial cell layer of the stomach, it is expected to become a new parameter of the morphological and functional integrity of these cells. In patients in whom severe functional and morphological alteration of the surface epithelium has been observed, the esterase secretion should be decreased, as evidenced in this study.

1255 AGE OF GASTRIC CANCER PATIENTS AND SUSCEPTIBILITY TO CHRONIC GASTRITIS IN THEIR RELATIVES. A MATHEMATICAL APPROACH USING POISSON'S PROCESS AND SCORING OF GASTRITIS STATE.

(E.) Kekki, M.; Ihamaki, T.; Varis, K.; Isokoski, M.; Lehtola, J.; Hovinen, E.; Siurala, M. (Dept.

Med., Univ. Helsinki, Finland). *Scand. J. Gastroenterol.* 8(7):673-679, 1973.

The results of morphological examination of the gastric body mucosa of 135 first-degree relatives of 33 index patients with gastric carcinoma and of 142 randomly selected subjects of a Finnish rural population were treated mathematically as follows. Each subject was given a score number depending on the state of gastric body mucosa (normal = 0, superficial gastritis = 1, atrophic gastritis = 2-4). The age specific prevalence curves of the random population were plotted on a scale obtained applying Poisson's process assumptions. An age-dependent score line was then derived from these curves. Individual score numbers for both series were subtracted from this line. Thus an age-adjusted score was obtained. It appeared that first-degree relatives of younger index patients with gastric carcinoma had significantly higher age-adjusted score values than the random population and older index patients. These results clearly suggest the significance of genetic component in the development of gastritis and at least partly suggest a genetically linked association between atrophic gastritis and gastric cancer. It is suggested that there may be 2 types of families with regard to liability to chronic gastritis, high risk and low risk families, the former composed mainly of families in which there are younger gastric cancer patients and the latter composed of families whose gastric cancer patients are older.

1256 ADENOCARCINOMAS OF STOMACH, PANCREAS, LIVER, AND BILIARY TRACTS: SURVIVAL OF 329 PATIENTS TREATED WITH FLUOROPYRIMIDINE THERAPY.

(E.) Davis, Jr., H. L.; Ramirez, G.; Ansfield, F. J. (Univ. Hosp. Madison, Wisc.). *Cancer* 33(1):193-197, 1974.

A series of 328 patients with advanced cancers of the stomach, pancreas, liver, and biliary tract were treated with intensive fluoropyrimidine therapy, including 5-Fluorouracil (5-FU), 5-fluoro-2'-deoxy-β-uridine, intra-arterial infusions of 5-FU, and 5-FU plus radiotherapy. Survival patterns were analyzed with particular emphasis on survival 1 year after treatment was begun. Patients with stomach cancer had median survivals of 5-7 1/2 months; over-all survival of more than a year was seen in 22%. Radiation therapy plus 5-FU was associated with slightly longer survival, as was prior resection of the primary tumor. Patients with pancreatic cancer survived four months median, with 12.5% surviving longer than 1 yr. Survival was dependent on the extent of the disease at the onset of therapy. Hepatobiliary cancer continued to present a very bleak prognosis. However, excellent responses occurred in 3/31 patients with liver cell or bile duct carcinoma. Intra-arterial infusions for liver involvement in these patients appeared to contribute little benefit to over-all survival, although dramatic responses were observed in two patients with primary liver tumors. It would appear that fluoropyrimidine therapy may modestly increase over-all survival in advanced stomach cancer. Survival in pancreatic cancer does not seem to be favorably influenced by this therapy.

1257 FAMILIAL GASTRIC CANCER AND IMMUNOLOGIC ABNORMALITIES.

(E.) Creagan, E. T.; Fraumeni, Jr., J. F. (Natl. Cancer Inst., Bethesda, Md.). *Cancer* 32(6):1325-1331, 1973.

Case reports, laboratory, and environmental studies are presented to study familial gastric cancer and immunologic abnormalities. Stomach cancer developed in 12 members of an inbred Anglo-Saxon family over 4 generations. The family resided in a rural, agricultural county in southwestern Virginia where the reported mortality from this cancer has been significantly higher than in the surrounding region. A high frequency of family members had evidence of cell-mediated immunodeficiency, manifested by impaired lymphocyte transformation *in vitro*, skin test anergy, and lymphocytopenia. The presence in several family members of parietal cell antibodies and macrocytosis suggests a subclinical process related to pernicious anemia, perhaps a genetically-mediated autoimmune gastritis predisposing to stomach cancer. Selective immunoglobulin deficiency was found in only 3 family members of this study, but each had subclinical evidence of gastrointestinal dysfunction: parietal cell antibodies in 2 cases, and a high concentration of alpha-fetoprotein in 1 case. In addition to stomach cancer, the following diseases occurred in 10 other family members: pernicious anemia, carcinoma of colon, systemic lupus erythematosus, adenoma of breast, mucous colitis, adenoma of thyroid and gastric ulcer. An epidemiological analysis revealed that the 35 deaths reported in this county (exclusive of members of the study family) were higher than the 22 expected from the surrounding counties, and the 26 expected from the United States rates. Soil analysis revealed nothing of a significant nature.

1258 ADENYL AND GUANYL CYCLASE IN RABBIT GASTRIC MUCOSA.

(E.) Sung, C. P.; Jenkins, B. C.; Burns, L. R.; Hackney, V.; Spenney, J. G.; Sachs, G.; Wiebelhaus, V. D. (Smith Kilne & French Lab., Philadelphia, Pa.). *Am. J. Physiol.* 225(6):1359-1363, 1973.

Adenyl and guanyl cyclase were studied in rabbit gastric mucosa. The presence of fluoride activates the adenyl cyclase of both fundic and antral mucosa between 5- to 10-fold. The addition of 1 mM histamine to the incubation medium results in a 2- to 5-fold stimulation of adenyl cyclase activity. This stimulation occurs in fundic mucosa, but not antral mucosa. The effect is dose responsive. At very high histamine (10^{-1} M) there is an inhibition showing only 60% of control activity. Studies of adenyl cyclase activity at various pHs revealed an optimum for both basal and histamine stimulated activity at pH 7.8.

variety of analogues of histamine were used o establish a correlation between gastric secreory activity and adenyl cyclase activation. There s a very good correlation bewteen effect in this ssay and effect on gastric acid secretion. Dihenylhydramine, burimamide, and mepyramine inhiited the histamine stimulation of adenyl cyclse activity but diphenylhydramine also blocked luoride stimulation. Mn^{++} inhibited the hisamine stimulation at 5 mM and increased the luoride activation. Guanyl cyclase was not stiulated by either histamine or fluoride. It is oncluded that the histamine-sensitive adenyl cyclse is a property of the tubular cell system and hat there is a distinct correlation between stiulation of the adenyl cyclase and stimulation of cid secretion.

259 MICROFLORA OF THE SMALL INTESTINE AND THE INCIDENCE OF LIVER DISEASE, STEATRRHOEA, AND INDICANURIA IN PATIENTS SUBJECTED TO ARTIAL GASTRECTOMY. *(E.)* Engstrom, J.; ellstrom, K. (Karolinska Inst., Stockholm, weden). *Acta Chir. Scand.* 139(6):539-545, 973.

spirates were obtained from the duodenum of 8 atients subjected to a Billroth I and from the fferent loop of 26 patients subjected to a illroth II gastrectomy. A normal microflora, efined as less than 10^3 of aerobic colonic organisms and less than 10^5 of common pharyngeal pecies/ml aspirate, was encountered in 3 Billroth I patients. Abnormal concentrations of erobic colonic bacteria were found in 3 of the illroth I and 20 of the Billroth II patients, hereas the aspirates from the remaining patents contained more than 10^5 of pharyngeal rganisms/ml. The proliferation of microorganisms in the upper small intestine was not ssociated with ascending cholangitis and liver disease as evidenced by the syptomatology, laboratory ests and the histological picture of the liver iopsy specimens. Neither were these microorgansms a major factor responsible for the malabsorption which often develops after partial gasrectomy. Steatorrhea and abnormal indicanuria ere observed in several patients, but there was o correlation between these findings and the oncentration of microorganisms in the aspirates. lthough deconjugated bile acids were found in nly the most proximal small intestine of a ew patients, the presence of abundant amounts of . *aerogenes* (bile salt-deconjugating organisms) n the aspirates was related to the incidence of teatorrhea.

260 THE EFFECT OF SECRETIN ON PLASMA CONCENTRATION OF GASTRIN IN FASTING PATIENTS WITH CARCINOMA OF THE STOMACH. *(E.)* Schrumpf, E.; Myren, J. (Aker Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 8(6):479-482, 1973.

The basal gastrin level in 10 patients with gastric carcinoma, of whom 4 were achlorhydric and 1 also suffered from pernicious anemia, was not significantly different from that in 6 achlorhydric subjects without carcinoma. A significantly smaller decrease of the basal plasma level of gastrin by secretin did occur, however, in 4 achlorhydric patients with gastric carcinoma than in 6 achlorhydric patients without carcinoma of the stomach. It is therefore questioned whether the gastrin-producing cells in achlorhydric patients with gastric carcinoma are autonomous and thus do not respond to physiological inhibitors like secretin. In 6 patients with gastric carcinoma without achlorhydria, secretin caused a significant decrease in the basal gastrin level, whereas no effect of secretin was seen on the gastrin level in 8 fasting normals. In speculating about the pathogenesis of gastric carcinoma in achlorhydria it is suggested that it may be the gastrin-producing cells, lacking the negative inhibition by the gastric acid secretion, which turn malignant.

1261 UNUSUAL COMPARATIVE FREQUENCY OF GASTRIC CARCINOMA, PERNICIOUS ANEMIA, AND PEPTIC ULCER IN SOUTHWESTERN AMERICAN INDIANS. *(E.)* Sievers, M. L. (Phoenix Indian Med. Ctr., Ariz.). *Gastroenterology* 65(6):867-876, 1973.

A comparison was made of the prevalence of gastric carcinoma, pernicious anemia, gastric ulcer and duodenal ulcer among patients at the Phoenix Indian Medical Center. During 17 yr, 129 patients presented with these 4 diseases. In comparison with rates for the general population, southwestern Indians approximated the expected numbers with gastric carcinoma and pernicious anemia, but had marked deficits for gastric and duodenal ulcer. All with gastric carcinoma, pernicious anemia, or gastric ulcer were Indian, but 26% of the 19 with duodenal ulcer were non-Indian, though the non-Indian admission rate was only 0.5%. Almost 1/3 of the 41 Indians with peptic ulcer had only partial Indian heritage, and 9 of those 13 had duodenal ulcer. Among full-blooded southwestern Indians, 90% of hospital admissions, 60 had gastric carcinoma; 18, pernicious anemia; 22, gastric ulcer; and 3, duodenal ulcer. In contrast with reported Caucasian experience, gastric lesions of Indians were much more likely (2.7:1.0) to be malignant than benign. This probability was highest (8.4:1.0) for the Hohokam (Pima-Papago). Except for a vast predominance of blood group O, southwestern Indians had attributes generally compatible with the observed infrequency of peptic ulcer and moderate prevalence of gastric carcinoma and pernicious anemia: rural reservation residence, lower socioeconomic level, noncompetitiveness, obesity, ABH salivary secretion, phenothiocarbamide taste sensitivity, high rates of diabetes mellitus and cholelithiasis, excessive drinking of alcohol, infrequent smoking of cigarettes, and low rates for chronic obstructure lung disease and coronary heart disease. It is suggested that detailed gastric secretory studies and observation of future disease patterns in southwestern Indians may increase the understanding of these disorders.

1262 SURGICAL RESULTS FOR EARLY GASTRIC CANCER. *(E.)* Yamada, E.; Nakazato, H.; Koike, A.; Suzuki, K.; Kato, K.; Kito, T. (Aichi Cancer Ctr. Hosp., Nagoya, Japan). *Int. Surg.* 59(1): 7-14, 1974.

The results of surgery for early gastric cancer are presented and discussed. A total of 1093 operations for gastric cancer were performed of which 195 were early (cancerous growth of the stomach wall confined to the mucosal or submucosal layer) cases. Gastrectomies were performed on 858 patients of whom 195 were early cancer patients. There were 127 males and 68 females. Early gastric cancers with extremely shallow ulcers were most frequent and were most often found on the lesser curvature with the gastric angle as its center. Intramucosal cancers did not show any lymph node metastases, but 18 submucosal cancers did show them. There were 25 cases with multiple lesions. Fifteen of 195 early gastric cancer cases died after operation; 2 deaths were due to unknown causes, 7 to apparent noncancerous causes, 1 to bile duct cancer, and 5 to apparent recurrence. The recurrent cases were all submucosal cancers, half ulcer type and half tumor type. Three cases showed hematogenous metastases and 3 had liver metastases. Three recurrent cases showed lymph node metastases and 2 did not, but 4 showed lymphatic vessel invasion. It is concluded that the important factors affecting recurrence in early gastric cancer generally are the depth of the cancer invasion, lymph node metastasis, and vascular invasion.

1263 MUCUS GASTRIC BEZOAR. *(E.)* Thompson, H.; Gregory, D. H. (Albuquerque VA Hosp., N.M.). *Gastrointest. Endosc.* 20(2):69-70, 1973.

A case report is presented of a 67-year-old white man with a massive and symptomatic mucus bezoar present in an unobstructed stomach. He appeared at the hospital, complaining of weight loss and early satiety. A barium contrast examination of the upper gastrointestinal tract showed a mass within the stomach which was consistent on all films and diagnosed as a malignant lesion. Fiberoptic gastroscopy was performed. A circumscribed, mucoid-appearing, yellowish-green mass was found adherent to the body of the stomach. The surface of the mass was more solid than the interior. The superficial crust was easily disrupted with rapid dispersement of large amounts of semisolid jelled inner clumps into the gastric lumen. Aspiration of some of this material and sections of the biopsied outer surface showed no evidence of vegetable fibers. The patient was given 0.1 N HCl (120 ml to 180 ml) with 5 crushed Cotazyme tablets a day. Symptoms of early satiety recurred 1 month later at which time a repeated barium contrast examination showed reappearance of the mass. The mass was again disrupted with the biopsy forceps. Oral enzymatic therapy was reinstituted and continued on an intermittent basis.

1264 DISTRIBUTION OF ABO AND RHESUS BLOOD GROUPS IN PATIENTS WITH GASTRIC CARCINOMA, WITH REFERENCE TO ITS SITE OF ORIGIN. *(E.)* Van Wayjen, R. G. A.; Linschoten, H. (Surg. Dept. Wilhelmina Gasthuis, Univ. Amsterdam, Netherlands). *Gastroenterology* 65(6): 877-883, 1973.

The ABO blood group composition of 874 patients with cancer of the stomach was compared with that in 4 control groups--2 groups of blood donors, and 2 of national servicemen. The percentage of blood group A was significantly higher in the patients than in the control groups. This was most pronounced in patients with tumors of the antrum. Rhesus blood group composition between patients and control subjects did not differ. A relation between ABO blood group, secretor status, and excretion of protein and immunoglobulins with the saliva seems to exist. These findings are probably related to correlations between ABO blood group and the serum level of intestinal alkaline phosphatase. High levels of serum concentration were found in persons with blood groups O and B, and low serum concentrations were found in persons with blood group A. A strong relation existed between serum level of intestinal alkaline phosphatase and the secretor status; in nonsecretors a low level was found. It is suggested that genetically determined defects in immune responsiveness associated with certain blood group constellations can increase the susceptibility for diseases, including malignancies. Such a relation is clearly visible in the gastrointestinal tract as can be understood by the specific immunological system of this tract and by the upper intestinal secretion of ABH blood group substances.

STOMACH

Peptic Ulcers

1296 HEMATOLOGIC ALTERATIONS FOLLOWING PARTIAL GASTRECTOMY. *(E.)* Shafer, R. B.; Ripley, D.; Swaim, W. R.; Mahmud, K.; Doscherholmen, A. (VA Hosp., Minneapolis, Minn.). *Am. J. Med. Sci.* 266(4):240-248, 1973.

Serum and red blood cell (RBC) levels of vitamin B_{12} and folic acid together with serum iron and total iron binding capacity were followed in 142 male patients, aged 25 to 82 yr, after partial gastrectomy. The follow-up period was from two months to 25 yr after surgery. Thirty-three patients had undergone the Billroth I procedure and 109, the Billroth II. Indications for partial gastrectomy included gastric ulcer in 36 patients, duodenal ulcer in 102, and gastric carcinoma in 4. Anemia, defined as a hemoglobin level of less than 13.6 g/100 ml in men, was documented as a complication of partial gastrectomy in 48% of these patients (69 of 142). Iron deficiency, subnormal iron binding saturation, and hypochromic microcytic indices of circulating RBC were present in 32% of the patients (45 of 142). Vitamin B_{12} deficiency occurred in 42% (60 of 142) and folic acid deficiency in 37% (53 of 142 patients). It appears that the anemia resulting from partial gastrectomy represents a complex interrelationship between iron, vitamin B_{12}, and folic acid deficiency. It is evident, however, that a sizable number of patients undergoing partial gastrectomy have no hematological alterations.

1297 BASAL AND STIMULATED Br^{82} INTRAGASTRIC SECRETION IN DUODENAL ULCER. *(E.)* Fodor, O.; Szantay, I.; Cotul, S.; Popescu, S. (3rd Med. Clin., Cluj, Rumania). *Rev. Roum. Biochim.* 10(5):179-184, 1973.

Intragastric secretion of ^{82}Br and the HCl output were investigated in 16 patients with active duodenal ulcers and in 13 controls under basal conditions and after maximal histamine (0.05 mg/kg) or insulin (15 U) stimulation. Basal gastric secretion was collected for 1 hr by continuous aspiration of gastric juice in separate samples taken at 15 min intervals after a single dose of 1 μCi/kg of Na^{82}Br was injected. In both the ulcer and control groups significant increases occurred in the concentrations and outputs of Cl$^-$ after maximal stimulation. ^{82}Br secretion did not vary appreciably and was not correlated with Cl$^-$ secretion. These results suggest differences in gastric secretion of halogens might be related to a selective activity of the gastric parietal cells for chlorine, iodine, and bromine.

1298 RELATIONS BETWEEN THE PEPSIN-ACID CORRELATION (K 25) AND THE GASTRIC SECRETORY ACTIVITY OF URINE FROM 65 PATIENTS WITH DUODENAL ULCERS. *(Fr.)* Bernades, P.; Corbic, M.; Dubrasquet, M.; Bonfils, S. (Bichat Hosp., Paris, France). *Biol. Gastroenterol. (Paris)* 6(3):225-230, 1973.

he pepsin output corresponding to 25 ml of primary
cid secretion (K 25) and gastric secretory activity
f the urine (GSU) were studied in 65 patients (63
en and 2 women, aged 16-72 yr) with duodenal ulcer.
f these patients, 46 had active ulcers (radiological
vidence of an ulcer niche and/or perforation dating
ack less than 15 days) and 19 had quiescent ulcers
history of ulcer and deformation of the duodenal
ulb without an ulcer niche). None of the patients
ad any evidence of Zollinger-Ellison syndrome.
o significant differences between the 2 groups of
atients were found for basal acid output, K 25, or
SU. Basal acid output ranged from 0.67 to 38.55
Eq/hr (mean 9.71 mEq/hr); K 25 values from 17 to 80
mean 44.8); and the test for GSU was negative in 21
ases, weakly positive in 28, and strongly positive
n 16. An inverse relation was found between the K 25
nd basal acid output. Basal acid output was signi-
icantly higher in patients with strongly positive
ests for GSU than in those with negative GSU tests,
hile K 25 values were significantly lower in patients
ith strongly positive GSU tests than in those with
egative and weakly positive tests. No strongly
ositive GSU was associated with a K 25 of more than
0. These findings suggest that hormonal factors
re involved in some cases of duodenal ulcer because
f the similarity between the K 25 and GSU relation
nd those found in Zollinger-Ellison syndrome.

299 STRESS AND ULCERATION IN THE GLANDULAR
AND NONGLANDULAR PORTIONS OF THE RAT'S
TOMACH. *(E.)* Mikhail, A. A. (Dept. Psychology,
. Manitoba, Winnipeg, Canada). *J. Comp. Physiol.*
sychol. 85(3):636-642, 1973.

he mechanisms underlying the formation of lesions
n the rumen and corpus of the rat stomach were
nvestigated in 24 rats of both sexes of the Maudsley
eactive and Nonreactive strains. Ulceration was
nduced in the corpus by partial restraint followed
20 hr of food deprivation (stage 1). Ulcers
isappeared when the rats were allowed to feed and
rink freely in their home cages for 72 hr. Rumenal
esions (stage 2) were produced by subjecting the
ats to conditioned fear (stimulation by light and
hock) for 72 hr (experiment 1) or for 48 hr (ex-
eriment 2). Seven of the 24 rats developed rumenal
esions. None of the sex, strain, or conditioned-
nxiety variables contributed significantly to
e development of lesions. The variable that
ppeared to be closely related to rumenal ulceration
s food deprivation. Rumenal lesions developed in
ne of the 12 rats which were not deprived of food
nd in seven of 12 rats which were deprived. The
echanisms of lesion formation in the glandular and
nglandular portions of the rat stomach are dif-
erent. In experiment 1, the pathophysiological
anges that led to rumenal ulceration were not
ufficient to induce lesions in the glandular re-
on, even when the region was the location of pre-
ous or existing damage. A period longer than 48
following stage 1 was necessary for the forma-
on of rumenal ulcers. The length of the latent
eriod seems to depend on variables which influence
e amount of the animal's food intake and the dura-
on of the deprivation period.

1300 PYLOROPLASTY VERSUS GASTROJEJUNOSTOMY: RESULTS OF A DOUBLE-BLIND, RANDOMIZED, CONTROLLED TRIAL. *(E.)* Kennedy, T.; Johnston, G. W.; Love, A. H. G.; Connell, A. M.; Spencer, F. A. (Roy. Victoria Hosp., Belfast, Northern Ireland). *Br. J. Surg.* 70(12):949-953, 1973.

A double-blind, randomized, controlled trial of 50 cases with Finney pyloroplasty and 50 with gastrojejunostomy, each with selective vagotomy, is reported. There were no operative deaths but 5 patients have subsequently died or have been lost to follow-up, leaving 94 patients, with a mean follow-up time of 3 1/2 yr. There has been 1 proven recurrence after gastrojejunostomy and 2 after pyloroplasty, with 1 further suspected recurrence in each group. The clinical grading marginally favored gastrojejunostomy. There was no significant difference in the incidence of bilious vomiting, dumping, diarrhea, or other disturbances, but there was a significantly greater increase in bowel frequency after pyloroplasty. Weight changes were similar, and there was no gross anemia or calcium deficiency in either group. Gastrojejunostomy is reversible and pyloroplasty is not, and therefore gastrojejunostomy is recommended as the drainage procedure of choice when drainage is necessary after vagotomy.

1301 GRADED VAGOTOMY AND GASTRIC SECRETION. *(E.)* Nundy, S.; Baron, J. H. (Roy. Postgrad. Med. Sch., London, England). *Am. J. Dig. Dis.* 19(2):137-142, 1974.

In 3 female mongrel dogs with gastric fistulae, partial denervation of the acid secreting area of the stomach halved the insulin-stimulated acid secretion. Completion of a highly selective (proximal gastric) vagotomy resulted in a further fall of the peak acid output after insulin to 4% of control values, and there was no further change when selective and truncal vagotomy were performed. The pentagastrin dose-response curve was shifted to the right after partial denervation and remained so shifted after subsequent operations. At low doses there was a considerable decrease in acid output, and the maximal acid output was unchanged but achieved only with a higher dose of pentagastrin. These results suggest that the gastric secretory response after vagotomy is not an all-or-none phenomenon and that the fall in peak acid output after insulin is related to the extent of the acid-secreting mucosa denervated. Tailored vagotomy operations might lower the acid secretion sufficiently to heal an ulcer without interfering with other aspects of gastrointestinal function.

SMALL INTESTINE

1318 VASCULAR MALFORMATIONS OF THE INTESTINE: AN IMPORTANT CAUSE OF OBSCURE GASTROINTESTINAL HEMORRHAGE. *(E.)* Heald, R. J.; Ray, J. E. (A. Ochsner Med. Fdn., New Orleans, La.). *South Med. J.* 67(1):33-38, 1974.

Case reports of 5 patients with bleeding vascular malformations of the gastrointestinal tract are presented and discussed. In each case, there was massive, unexplained bleedings. In 4 patients, at least one completely ineffective laparotomy was performed, and in 1 the distral two thirds of the stomach was excised uselessly. In the first case, a purple knob, 1 cm in diameter was discovered on the posterior aspect of the left end of the transverse colon. Local resection of the splenic flexure revealed this small hemangioma which penetrated muscle and submucosa and was clearly ulcerated on its mucosal aspect. Examination of the second patient revealed 3 small capillary hemangiomas on the skin. A blind total colectomy and ileorectal anastomosis were performed. On the mucosa of the lateral wall of the cecum were 2 areas of pigmentation. One was slightly raised and proved to be an adenoma. The other was small, flat and black, only a few millimeters in diameter, and proved to be a hemangioma. The third patient had a laparotomy during which it was found that the jejunum had dilated and there were prominent veings on the surface. The patient was cured by the resection of the worst part of this abnormal small bowel. For the fourth patient, selective celiac angiography was performed and the radiologist reported a small area of abnormal circulation and a small extravascular stain of contrast in the lower esophagus. A small circular disk of esophageal wall was resected and revealed a small vascular hamartoma. The fifth patient had a superior mesenteric arteriogram which revealed an arteriovenous malformation in the region of the cecum. Right hemicolectomy was successful in stopping the bleeding. The small size and vascular nature of these lesions make the diagnosis by routine roetgenographic studies difficult. Selective mesenteric angiography is probably the best diagnostic aid. When such a lesion is suspected and all radiographic studies are negative, blind right colectomy is more apt to cure the patient than any other procedure.

1319 ENDOMETRIOSIS OF THE SMALL INTESTINE. PRODUCING INTESTINAL OBSTRUCTION OR SIMULATING NEOPLASM. *(E.)*

LiVolsi, V. A.; Perzin, K. H. (Columbia Univ. Coll. Physicians Surgeons., New York, N.Y.). *Am. J. Dig. Dis.* 19(2):100-108, 1974.

Five cases of endometriosis of the small intestine are presented in which the diagnosis of small intestinal neoplasm was strongly considered clinically. The patients ranged in age from 25 to 48 yr. They were pre- or perimenopausal. Three patients were nulliparous at the time of diagnosis; a fourth woman had 1 child and 1 abortion. The fifth individual gave a history of 2 successful pregnancies and 1 abortion. The symptoms included crampy pain, localized to the lower abdomen. The discomfort had been noted for between 3 weeks and 6 months. Each episode produced increasingly severe symptoms. In each of the 5 cases, endometriosis of the ovaries and/or Fallopian tubes was seen grossly at operation. Histological study of an ovary removed from one patient demonstrated endometriosis. Three cases had produced localized intramural masses, resembling a neoplasm; one of these had also caused partial involvement of a segment of ileum with mural thickening and luminal narrowing, leading to obstruction. The primary treatment was resection of the involved segment of bowel. None of the patients had a previous diagnosis of endometriosis, and none received hormonal medication nor castration. After resection of the involved small intestine, all 5 patients are free of intestinal symptoms for from 2 months to 13 yr.

1320 HYPERSECRETION OF GASTRIN ASSOCIATED WITH THE SHORT BOWEL SYNDROME. *(E.)*

Straus, E.; Gerson, C. D.; Yalow, R. S. (VA Hosp., Bronx, N.Y.). *Gastroenterology* 66(2): 175-180, 1974.

The possible role of gastrin in the acid hypersecretory state which is associated with the short bowel syndrome was assessed in 13 subjects, 4 with short bowel syndrome, 1 after jejunoileal bypass surgery for obesity, and 8 normal subjects. After an overnight fast, all subjects received a standard test meal consisting of 2 hard-boiled eggs, 1 slice of dry white toast, and 120 ml of orange juice. Plasma samples were obtained ar 15, 10 and 5 min prior to feeding and at 5, 10, 15, 20, 30, 40, 60, 90, and 120 min after completion of the meal. The mean values for basal and peak postprandial gastrin concentrations in the 8 control subjects were 43 pg/ml and 96 pg/ml, respectively. In all 4 patients with the short bowel syndrome, marked hypergastrinemia, characterized by high fasting levels, and a prompt sharp response to the standard test meal were observed. Fasting gastrin concentrations ranged from a low of 96 pg/ml to a high of 610 pg/ml. Three patients did not have gastrectomy, the times of the peak gastrin levels for them were achieved between 15 and 40 min, coinciding with the times of peak concentrations observed in the control group. The subsequent rate of fall after the peak appeared to be even more rapid in these 3 subjects than in the control group. It is concluded that these results are consistent with the possible existence of a factor in the distal small intestine that may play a role in inhibiting gastrin release.

1321 PREJEJUNAL TRANSPOSITION OF COLON TO PREVENT THE DEVELOPMENT OF SHORT BOWEL SYNDROME IN PUPPIES WITH 90 PER CENT SMALL INTESTINE RESECTION. *(E.)*

Hutcher, N. E.; Mendez-Picon, G.; Salzberg, A. M. (Med. Coll. Virginia, Richmond). *J. Pediatr. Surg.* 8(5):771-777, 1973.

The effect of colon transposition when jejunum was the principal segment remaining after resection was studied in purebred male beagle puppies. Group 1 (2 animals) consisted of the nonoperated controls. Group 2 (6 animals) underwent a 90% resection of small intestine, which left 7.5% proximal jejunum and 2.5% distal ileum. The ileocecal valve remained intact. Group 3 (6 animals) underwent an identical 90% resection of small intestine. The small intestinal continuity was reestablished. This was followed with transposition of an isoperistaltic colon segment between the fourth portion of the duodenum and the remaining small intestine. There were 2 operative deaths. The growth curve of the nonoperated controls forms the basis for predicting the growth of the operated animals. At the end of the 66-week study period, the animals weighed 10.2 kg. Animals in group 2 with 90% small-intestinal resection underwent resection at a mean age of 14.2 weeks and weighed 3.4 kg. A mean length of 24 cm of small intestine remained after resection. Of the 5 operative survivors, there were 2 nutritional deaths. They died at 58 and 80 days postoperatively. At time of death they had lost 31% of their preoperative body weight and were only 32.5% of their predicted weight. The remaining 3 animals were followed for 1 yr postoperatively. By the third postoperative month they had all regained their preoperative weight and over the next 9 months exceeded that weight by a mean of 53%. They attained 50.6% of their predicted weight at the end of the first postoperative year. The group 3 animals with 90% resection plus colon transposition had a mean length of 13.2 cm of colon transposed proximal to the mean length of 25 cm of small intestine remaining after resection. All animals exceeded their preoperative weight by a mean of 85%. Both Groups 2 and 3 developed a microcytic hypochromic anemia. All resected animals had delayed gastric emptying and decreased pylorus-to-cecum transit time. The stools from animals in Groups 2 and 3 were loose and bulky. It is concluded that the merit of colon transposition in modifying the clinical course after a 90% small-intestine resection leaving primarily jejunum is demonstrated.

1322 MALACOPLAKIA: AN ELECTRON-MICROSCOPIC STUDY: DEMONSTRATION OF BACILLIFORM ORGANISMS IN MALACOPLAKIC MACROPHAGES. *(E.)* Lewin, K. J.; Harell, G. S.; Lee, A. S.; Crowley, L. G. (Stanford Univ. Sch. Med., Calif.). *Gastroenterology* 66(1):28-45, 1974.

A case of malacoplakia of the bladder and intestinal tract is reported in which bacilliform organisms were demonstrated within the malacoplakic macrophages by light and electron microscopy. The female patient first presented at age 42 yr with generalized lymphadenopathy. Two yr later she presented with generalized lymphadenopathy, splenomegaly, and a mass lateral to the right breast. Five months later she developed an *Escherichia coli* urinary tract infection, unresponsive to numerous antibiotics. Cystoscopy 3 months later for continued cystitis revealed the entire bladder dome and the left lateral bladder wall to be involved by a fungating, firm, sessile, necrotic mass. Biopsy showed malacoplakia. Three months later, work-up for recurrent adenopathy revealed a recurrence of the right lateral breast mass, splenomegaly, and bilateral inguinal adenopathy. Lymphangiography demonstrated abnormal pelvic and para-aortic nodes consistent with lymphoma. Radiation therapy was delivered over a 2-week period. Her terminal admission was about a yr later with a white blood count of 500 mm and a hematocrit of 23%. She died 3 days after admission with pneumonia and renal failure. Protein electrophoresis and quantitative immunoglobulins revealed abnormally low immunoglobulin values. On electron microscopy, 2 types of cytoplasmic inclusions were found, those corresponding to the periodic acid Schiff-positive granules which are phagolysosomes, and the Michaelis-Gutmann bodies. Bacteria, probably coliforms, in various stages of degradation, were present within phagocytic vacuoles and phagolysosomes, sometimes in close apposition to phospholipid membranes. The Michaelis-Gutmann bodies developed within the phagolysosomes. It is postulated that the following sequence of events occurs in the pathogenesis of Michaelis-Gutmann bodies. Bacteria are phagocytosed by the malacoplakic macrophages, incorporated into phagolysosomes, and killed, but are incompletely digested. They persist as dense amorphous aggregates and phospholipid membranes which later become encrusted with calcium phosphate crystals to form the laminated Michaelis-Gutmann bodies. It is proposed that this case of malacoplakia was associated with altered immune status. The patient had lymphocytic lymphoma, which may be associated with depressed cell-mediated immunity, and, to a lesser degree, depressed immunoglobulin production. The patient's treatment consisted of long-term steroids and chlorambucil, both of which are lympholytic agents, and chlorambucil is a powerful immunosuppressant. Terminally, the patient was severely emaciated, and this may also have contributed to her depressed immunoglobulins.

SMALL INTESTINE

Malabsorption

1339 FATTY ACID COMPOSITION OF PLASMA LIPOPROTEINS IN CONTROL SUBJECTS AND IN PATIENTS WITH MALABSORPTION. *(E.)* Shimoyama, T.; Kikuchi, H.; Press, M.; Thompson, G. R. (Hyogo Coll. Med., Japan). *Gut* 14(9):716-722, 1973.

The fatty acid composition of plasma lipids and lipoproteins was studied in fasting blood samples taken from 14 normal controls, 5 patients with diseases other than malabsorption, and 24 patients with intestinal malabsorption. Malabsorption resulted from intestinal resection in 6 patients, adult celiac disease in 12, and from other causes (pancreatic dysfunction, intestinal lymphangiectasia, and blind-loop syndrome) in 6. All patients were on a normal ward diet with the exception of 3 patients with celiac disease who were on a gluten-free diet. The lineolate content of plasma lipids was significantly lower in patients with malabsorption than in normal controls. This decrease was more evident in the percentage composition of the fatty acids of lecithin and cholesterol ester than that of the triglyceride fraction and was accompanied by reciprocal increases in the proportion of saturated and monounsaturated fatty acids. Many of these patients had reduced concentrations of cholesterol ester, triglyceride, and phospholipid so that there was often an absolute as well as a proportional decrease in plasma linoleate. The observation of similar, but less pronounced, differences in sick controls suggests that malabsorption of dietary linoleate is not the only factor involved. A reduced intake of fat probably played a major role in both groups of patients, and nonspecific hepatic dysfunction which commonly accompanies fevers could have been a contributory factory among the sick controls. Among the patients with malabsorption, changes in the plasma fatty acid composition were more marked in patients with intestinal resection than in those with adult celiac disease or steatorrhea due to other causes. This difference was apparently not related to the severity of the malabsorption since steatorrhea was least marked in the resection group; there was no correlation with the duration of the illness. Unequivocal evidence of fatty acid deficiency, defined as the presence of significant amounts of eicosatrienoic acid in plasma lecithin, was observed with a concomitant decrease in arachidonate in only 2 patients. The failure to find differences in the fatty acid composition of different classes of lipoproteins (high-density, low-density, and very low-density) in patients with malabsorption suggests that differences between the cholesterol esters are due to preferential incorporation of linoleate into low- and high-density lipoproteins. It is concluded that some degree of essential fatty acid depletion is common in hospitalized patients, whether or not they have malabsorption. Actual deficiency, however, is much less common and appears to occur primarily in patients who have malabsorption secondary to intestinal resection.

1340 PROTEIN SYNTHESIS BY HUMAN INTESTINAL MUCOSA: VARIATIONS WITH DISEASES OF THE GUT.

(E.) Warshaw, A. L.; Laster, L. (Digestive Hereditary Dis. Br., Natl. Inst. Health, Bethesda, Md.). *J. Surg. Res.* 14(4):285-293, 1973.

Studies of protein synthesis by human intestinal mucosa were performed by determining the *in vitro* incorporation of U-^{14}C-L-leucine into total proteins of peroral mucosal biopsy specimens. The mean value for normal mucosa was 1483 cpm/mg/30 min. In mucosa from 5 patients with celiac disease the mean value for mucosal protein synthesis was 3056 cpm/mg/30 min, a significant elevation, perhaps reflective of abnormally high cell turnover in this disease. In mucosa from 2 patients with abetalipoproteinemia the mean value for protein synthesis was 535 cpm/mg/30 min. This value, which is significantly lower than normal, may be related to diminished or absent synthesis of betalipoproteins by the intestine in this disease. The mean value for mucosal protein synthesis among 5 patients with treated Whipple's disease in remission was normal. Patients with regional enteritis (2 females) were also studied. In one patient the entire small intestine was involved and increased loss of plasma protein into the gastrointestinal tract was occurring. Steatorrhea amounted to about 10-20% of the dietary fat intake. The value for incorporation of leucine-U-^{14}C into protein by mucosa from these 2 women was 2800 to 2192 dpm/mg/30 min. Measurement of protein synthesis by intestinal mucosa obtained by peroral biopsy appears useful in assessing metabolic aberrations and adaptations of the gut.

1341 MUCOSAL SECRETORY IgA AND SECRETORY PIECE IN ADULT COELIAC DISEASE.

(E.) Shiner, R. J.; Ballard, J. (Central Middlesex Hosp., London, England). *Gut* 14(10):778-783, 1973.

Immunofluorescence studies with specific antisera to secretory IgA (11S IgA) and secretory piece (a glycoprotein found in the gastrointestinal epithelial cells) were performed on the jejunal mucosa of 9 patients, aged 16 to 56 yr, with adult celiac disease (treated and untreated). The jejunal biopsies from 8 non-celiac patients, aged 13 to 59 yr, served as controls. Four of these patients had no gastrointestinal disease; the other 4 had local and systemic IgA (7S) deficiency with normal villous architecture. In untreated celiac patients, fluorescent staining with antisera to 11S IgA and secretory piece was seen in the basement membrane of surface and crypt epithelial cells and the surrounding connective tissue, as well as in the upper third of the epithelial cells where it is normally found. In the 5 treated celiac patients, staining was mainly confined to the upper third of the epithelial cells. The distribution of staining seemed to be related to the histological state of the jejunal mucosa in the celiac patients. In those patients with a subtotal villous atrophy, staining of the basement membranes and connective tissue, as well as the upper third of the epithelium, was observed. In those with milder mucosal abnormalities (partial villous atrophy), who were on low-gluten diets, the 11S IgA and secretory piece showed a normal distribution. It is proposed that in normal situations, locally produced 7S IgA passes through the intercellular spaces to enter the upper third of the epithelium where it combines with secretory piece to form 11S IgA. This is then transported across the microvilli into the lumen. An additional pathway is proposed in pathological states in which a backflow of 11S IgA from the epithelium to the lamina propria occurs. The exact site of 11S IgA formation in celiac disease is not known, but it probably occurs in the upper third of epithelial cells as in normal patients.

1342 A SIMPLE THIN-LAYER CHROMATOGRAPHIC TECHNIQUE FOR THE ASSAY OF INTESTINAL DIPEPTIDE HYDROLASES FROM HUMAN MUCOSAL BIOPSY MATERIAL.

(E.) Lentze, M.; Schaub, J.; Harms, K. (Children's Clin., Univ. Munich, Germany). *Clin. Chim. Acta.* 49:19-26, 1973.

Specimens of intestinal mucosa were obtained from 60 children ranging in age from one month to 6 yr. The children were divided into 4 groups: (1) 22 controls; (2) 10 children with clinical signs of untreated celiac disease; (3) 16 children with treated celiac disease; and (4) 12 children with malabsorption syndrome. The homogenized specimen was mixed with the same volume of dipeptide substrate in a pH 8.5 phosphate-citrate-borate buffer and was incubated at 37°C. Ascending thin-layer chromatography was performed with a mixture of pyridine-dioxane-25% ammonia-water (35:35:15:15) for all substrates except glycine-glutamine, for which a mixture of phenol and formic acid (15%) was used. Dipeptides and the corresponding amino acids were located by staining with a ninhydrin solution. The activities of 11 dipeptide hydrolases and the disaccharidases maltase, isomaltase, sucrase, and lactase were measured. Human intestinal mucosa hydrolyzed the dipeptides, tryptophan-tyrosine and alanine-leucine. Enzymes hydrolyzing these substrates were decreased in children with untreated celiac disease and were nearly normal after treatment with a gluten-free diet. With the exception of valine-glutamic acid and valine-proline dipeptide hydrolases, activities of the dipeptide hydrolases were normal or only slightly decreased in group (3). Lactase deficiency was diagnosed in 70% of the patients in group (2). The activity of lactase was lower than the activities of isomaltase, maltase, and sucrase in group (3) patients. Decreased lactase activity was also found in 41% of the children in group (4). The advantage of thin-layer chromatography over the amino acid oxidase method is that the former can be used to detect glutamic acid, proline, alanine, asparagine, glycine, and hydroxyproline, while the latter cannot.

1343 ECTOPIC GASTRIC MUCOSA IN CELIAC SPRUE. *(E.)* Trier, J. S.; Moxey, P. C.; Fordtran, J. S.; MacDermott, R. P. (Boston Univ. Sch. Med., Mass.). *Gastroenterology* 65(5):712-727, 1973.

A 56-year-old female patient with celiac sprue and extensive gastric ectopia of the small intestine is described. The diagnosis of celiac sprue was documented by: the presence of a typical mucosal lesion and intestinal malabsorption; clinical and histological improvement after gluten withdrawal; and recurrence of symptoms together with histological deterioration after an oral gluten challenge. Fundic-type gastric mucosa containing parietal and chief cells was found in the mucosa of all sampled levels of the small intestine including proximal and distal duodenum, proximal, middle, and distal jejunum, and proximal ileum. Jejunal perfusion demonstrated secretion rather than absorption of water and electrolytes, diminished glucose absorption, and a markedly reduced ratio of urea to tritiated water diffusion rates. Although there was no evidence of hydrogen ion secretion by the parietal cell-containing jejunal mucosa during the basal state, bicarbonate absorption occurred during both histamine and pentagastrin infusion, suggesting a limited amount of acid secretion during stimulation.

1344 HL-A1 AND HL-A8 ANTIGENS ASSOCIATED WITH CELIAC DISEASE IN CHILDREN. *(Ger.)* Ludwig, H.; Polymenidis, Z.; Granditsch, G.; Wick, G. (Inst. Immunol., Univ. Vienna, Austria). *Z. Immunitaetsforsch.* 146(2):158-167, 1973.

The histocompatibility antigen (HL-A) phenotype was established by the micro lymphocyte toxicity test for 24 children, aged 6 months to 14 yr, with celiac disease diagnosed by history and clinical findings, direct and indirect laboratory evidence of malabsorption, small intestine biopsy, response to gluten-free diet, and immunofluorescence examination of sections from small intestine biopsies. Controls consisted of 240 candidates for kidney transplants, kidney donors, and blood donors; none of the controls was related to the patients with celiac disease or to one another. HL-A1 was present in 15 (62.5%) and HL-A8 in 16 (66.7%) of the children with celiac disease, but in only 71 (29.6%) and 39 (16.3%) of the controls, resp. This difference is statistically significant. Both antigens were present in 14 of the 24 patients with celiac disease. The genotypes of 13 children were established by tissue typing of 11 families. HL-A8 was present in 10 of these 13 children and was associated with HL-A1 in 9 of the 10. The two antigens were found to be inherited as a haplotype, either from the father or the mother. The haplotype HL-A1,8 was also found in 3 normal siblings of these children. The HL-A1,8 haplotype is not a direct cause of celiac disease, but must be associated with other, unknown factors for the disease to develop.

1345 AN IN VITRO MODEL OF GLUTEN-SENSITIVE ENTEROPATHY: EFFECT OF GLIADIN ON INTESTINAL EPITHELIAL CELLS OF PATIENTS WITH GLUTEN-SENSITIVE ENTEROPATHY IN ORGAN CULTURE. *(E.)* Falchuk, Z. M.; Gebhard, R. L.; Sessoms, C.; Strober, W. (Natl. Cancer Inst., Bethesda, Md.). *J. Clin. Invest.* 53(2):487-500, 1974.

Jejunal biopsy specimens from 11 patients with gluten-sensitive enteropathy (obtained during gluten challenge), 11 normal individuals, and 3 patients with other gastrointestinal abnormalities were cultured *in vitro* for 48 hr in the presence or absence of a peptic-tryptic digest of gliadin. In the absence of gliadin, alkaline phosphatase activity in the biopsy specimens from normal control individuals increased from an initial value of 384 U to a 48 hr value of 561 U. The initial alkaline phosphatase activity of specimens from patients with gluten-sensitive enteropathy was lower than that of normals, 117 U, and increased to a 48 hr value of 399 U. The biochemical change in cultured biopsy specimens of gluten-sensitive enteropathy patients correlated with increases in the length and regularity of brush borders of epithelial cells as seen with the electron microscope. In the presence of a peptic-tryptic digest of gliadin, alkaline phosphatase activity of biopsy specimens of control individuals increased from an initial value of 384 U to a 48 hr value of 578 U. In contrast, the alkaline phosphatase activity of biopsy specimens of patients with gluten-sensitive enteropathy in exacerbation showed a markedly diminished increase in activity during 48 hr of culture; in this case initial activity was 117 U and final activity was 203 U. This inhibitory effect on increase of alkaline phosphatase activity during organ culture was specific in that a peptic-tryptic digest of casein (a protein not toxic *in vivo* to patients with gluten-sensitive enteropathy had no effect on alkaline phosphatase increases in culture. These results obtained with biopsy specimens from gluten sensitive patients in exacerbation were compared with results obtained from patients with gluten-sensitive enteropathy in remission. Alkaline phosphatase activity of specimens from the latter group of patients also increased during culture bu but in this instance peptic-tryptic digest of gliadin in the culture medium had no significant inhibitory effect. The inhibitory effect of gliadin on intestinal epithelial cells in organ culture represents an *in vitro* model of gluten-sensitive enteropathy. As this effect of gliadin is not seen in cultures of specimens from patients in remission, it appears that gliadin is not directly toxic to gluten-sensitive enteropathy jejunal mucosa per se, but rather toxicity requires the participation of an endogenous effector mechanism which must first be stimulated *in vivo*.

1346 A NEW SYNDROME OF BILE ACID DEFICIENCY: A POSSIBLE SYNTHETIC DEFECT. *(E.)* Powell, G. K.; Jones, L. A.; Richardson, J. (Univ. Texas Med. Branch, Galveston). *J. Pediatr.* 83(5): 758-766, 1973.

A case report is presented of a 3-month-old infant with chronic diarrhea, failure to thrive, and severe malabsorption of fat (50%) who had low concentrations of bile acids in the duodenal fluid, with poor micellar incorporation of fatty acids. The deficiency of intraluminal bile acids was not due to (1) liver disease, (2) deconjugation of bile acids associated with bacterial overgrowth, (3) failure of intestinal reabsorption of bile acids, (4) failure of release of cholecystokinin, or (5) an excretion defect of bile acids. A trial of oral administration of bile acids produced increases in weight gain, absorption of fat, intraluminal micellar incorporation, and concentrations of intestinal bile acids. All of these returned to pretreatment values within a few days after discontinuance of administration of bile acids. A defect in the biosynthesis of bile acids, not secondary to liver disease, is suggested.

1347 CYSTIC FIBROSIS AND COELIAC DISEASE. REPORT OF TWO CASES. *(E.)* Taylor, B.; Sokol, G. (Hosp. Sick Children, London, England). *Arch. Dis. Child.* 48(9):692-696, 1973.

Two cases of celiac disease occurring in children with cystic fibrosis are presented. The disacchridase levels in duodenal biopsies from the first child included: lactase, 0.15; sucrase, 0.54; and maltase, 5.8. After 1 yr on a gluten free diet the respective figures were 0.2, 1.3, and 4.9. For the second child, lactase was 0.1; sucrase, 0.4. After 9 months on the gluten free diet, the respective figures were: 0.9 and 2.8. Normal value for lactase is over 2.5; for sucrase, over 3.0; and for maltase, over 10.0. Crystic fibrosis was diagnosed in both children through high sweat sodium levels. The 2 main theories as to the pathogenesis of coeliac disease involve the immunological status and a postulated toxic action of gluten on small intestinal mucosa associated with a congenital absence of a peptidase concerned in gluten digestion. Gluten intolerance might be more likely with abnormal pancreatic exocrine function. Intestinal wall enzymes may be deficient as well in cystic fibrosis. The values of intestinal disaccharidases improved in each case on the gluten free diets, but not to normal values. The coexistence of cystic fibrosis and celiac disease in association with low disaccharidase levels lends some support tp the theory of enzyme deficiency playing a part in the causation of celiac disease.

1348 PLASMA GROWTH HORMONE IN COELIAC DISEASE. *(E.)* Vanderschueren-Lodeweyckx, M.; Wolter, R.; Molla, A.; Eggermont, E.; Eeckels, R. (Dept. Pediatr., Catholic Univ., Louvain, Belgium). *Helv. Paediatr. Acta* 28(4):349-357, 1973.

Insulin tolerance tests were performed in 60 normal prepubertal children, 13 patients with active celiac disease and 4 treated subjects with gluten intolerance. Plasma levels of glucose, growth hormone and cortisol were followed. In untreated patients, the fall of blood glucose compared well to that of normal children, but there was no responsiveness to hypoglycemia. Gluten-free diet restored the normal responsiveness. In 9 of 13 untreated celiac subjects the maximal level of plasma growth hormone was below the mean -2SD of the values observed in normal subjects. In 3 of 4 treated celiac patients plasma growth hormone increased normally. However, 1 treated patient, who did not grow satisfactorily, showed a blunted response of plasma growth hormone. Plasma cortisol rose normally during the first 60 min in the patients with active celiac disease, but remained high up to 120 min. These results indicate that gluten enteropathy results in some degree of pituitary hypofunction perhaps due to decreased synthesis and release of somatotropic releasing factor by the hypothalamus and by a depressed production and release of somatotropic hormone by the pituitary gland. Thus it is necessary to exclude celiac disease whenever the release of growth hormone, following the administration of insulin, is impaired.

1349 TRANSIENT LACTOSE INTOLERANCE IN INFANCY. *(E.)* Bartrop, R. W.; Hull, D. (Hosp. Sick Children, London, England). *Arch. Dis. Child.* 49(12):963-966, 1973.

Transient lactose intolerance in infancy was examined in 100 infants with disaccharide intolerance secondary to a variety of bowel disorders. The primary diagnoses of the 100 infants with diarrhea which improved when lactose was removed from the diet include: infective diarrhea, nonspecific diarrhea, bowel surgery, gluten enteropathy, cystic fibrosis, and miscellaneous. The majority of infants who showed features of intolerance were less than 3 months old. The infants were maintained on a disaccharide free diet for over 40 weeks. However, reintroduction after 2 months was successful in 20 out of

22 children in whom it was attempted. The infants given sugar-free diets for over one year usually suffered from gluten enteropathy. Successful reintroduction of cow's milk occurred in 83 children, the diet being continued at follow-up in 8 others. Four children died from the primary pathology. Five children (4 with infective and nonspecific diarrhea, 1 with gluten enteropathy) had periods of bowel rest from several days to 2 weeks, followed by the gradual reintroduction of milk feeds containg disaccharide. The analysis suggested that infancts with troublesome, persistent diarrhea under the age of 6 months should be treated with a lactose-free diet, but that lactose might be introduced once the the child is thriving and stools have returned to normal consistency.

1350 PLASMA LIPID AND LIPOPROTEIN ABNORMALITIES IN PATIENTS WITH MALABSORPTION. *(E.)* Thompson, G. R.; Miller, J. P. (Hammersmith Hosp., London, England). *Clin. Sci. Mol. Med.* 45(5):583-592, 1973.

Plasma lipids and lipoproteins were studied in 16 control subjects and 24 patients with various types of steatorrhoea, including: intestinal resection, adult coeliac disease, carcinoma of pancreas, chronic pancreatitis, intestinal lymphangiectasia, and blind loop. Low plasma cholesterol levels were found in malabsorbers and were associated with decreased amounts of low-density lipoprotein (LDL) in males and high-density lipoprotein (HDL) in females. Serum triglyceride levels were normal in males, but exceeded control values in some of the females, due to an increase in very low-density lipoprotein. LDL composition was abnormal in both male and female malabsorbers, with a decreased proportion of cholesterol ester and an increased proportion of triglyceride. There was also an increased proportion of triglyceride in HDL. These findings show that malabsorption markedly influences not only the concentration but also the composition of plasma lipoproteins.

1351 LACTOSE MALABSORPTION IN OKLAHOMA INDIANS. *(E.)* Bose, D. P.; Welsh, J. D. (Oklahoma State Univ., Oklahoma City). *Am. J. Clin. Nutr.* 26(12):1320-1322, 1973.

Lactose malabsorption was studied in 41 American Indians of various tribes. There were 36 adults (age 18 to 57 yr) and 5 children (age 3 to 22 months). Thirty-seven had only an oral lactose tolerance test (LTT). 2 had only an assay of intestinal enzymes, and 2 had both the LTT and assay. LTTs were performed using 1 g lactose/kg body wt. Capillary blood glucose was determined by the Nelson-Somogyi method, and a rise of blood glucose of 20 mg/100 ml or less was considered to indicate lactose malabsorption. Twenty-nine of the 36 adults (80%) and none of the 5 children had lactose malabsorption. Of the 24 adults who were symptomatic, 10 recognized intolerance to milk previously. Seven drank no milk at all and therefore could not indicate whether or nor they were symptomatic. Thirty-one of the 36 adults drank less than 1 qt of milk/week. There was no apparent relationship between present milk drinking and lactose absorption. The mean blood glucose rise for the 7 adult absorbers was 41 mg/100 ml, and the 29 adult non-absorbers had a mean rise of 7 mg/100 ml. Two of the absorbers and 24 of the non-absorbers had symptoms. It is concluded that the majority of adult American Indians of North America are lactose intolerant. Therefore, milk drinking habits within this ethnic group need further consideration.

1352 LACTOSE FEEDING IN LACTOSE-INTOLERANT MONKEYS. *(E.)* Wen, C.; Antonowicz, I.; Tovar, E.; McGandy, R. B.; Gershoff, S. N. (Harvard Sch. Publ. Hlth., Boston, Mass.). *Am. J. Clin. Nutr.* 26(11):1224-1228, 1973.

1353 PROTEIN-LOSING ENTEROPATHIES OF LYMPHATIC ORIGIN: PART 1. SYMPTOMATOLOGY AND EXAMINATION. *(Fr.)* Fortas, L.; Frexinos, J. (Purpan Hosp., Toulouse, France). *Arch. Fr. Mal. App. Dig.* 62(6):501-512, 1973.

1354 MUSHROOM INTOLERANCE CAUSED BY SELECTIVE MALABSORPTION OF TREHALOSE. *(Fr.)* Bergoz, R. (Univ. Cantonal Hosp., Geneva, Switzerland). *Rev. Fr. Gastroenterol.* (86):29-34, 1973.

1355 DRUG-INDUCED MALABSORPTION. *(E.)* Kendall, M. J.; Chan, K. (Queen Elizabeth Hosp., Birmingham, England). *Xenobiotica* 3(11):727-744, 1973.

1356 NECROTIZING COLITIS. *(E.)* Rosen, I. B.; Cooter, N. B.; Ruderman, R. L. (Univ. Toronto Med. Sch., Canada). *Surg. Gynecol. Obstet.* 137(4):645-649, 1973.

Gross examinations were made of colon specimens from 5 patients with gangrene of the colon which was thought to be ischemic in nature; no mesenteric vascular occlusion was detected. Findings included normal-looking intestine, thickened edematous intestine with mucosal ulceration, and obvious gangrenous colon. Only one patient recovered after surgery. The mucosa in all cases was more severely affected than would be expected from the serosal aspect of colon. Mixed gram-positive and gram-negative organisms were found in necrotic mucosa, and occasionally in the submucosa and lumen of submucosal vessels. All of the patients were over 55 yr old and were afflicted with such conditions as asthma, bronchitis, Parkinson's disease, and rheumatoid arthritis. Prodomic symptoms of abdominal pain, distention, and constipation were common. Constipation, fevers of one or two degrees, vomiting of bile-stained fluid, toxicity, and generalized peritonitis with findings most marked in the left lower quadrant of the abdomen developed in the acute phase of this condition. Low grade leukocytosis and elevation of the blood urea nitrogen level were present in all patients. On x-ray examination, necrotizing colitis resembled perforated diverticulitis with a pseudovolvulus appearance. The best treatment consists of adequate resection, temporary stomas, and delayed union of the intestine. Left untreated, necrotizing colitis is lethal.

1357 SEGMENTAL DISEASES OF THE COLON ABOVE STENOSING NEOPLASMS. *(It.)* Puglionisi, A.; Asole, F.; Mantovani, M. (Inst. Special Surg. Pathol., Sacred Heart Catholic Univ., Rome, Italy). *Chir. Gastroenterol.* 7(1):47-66, 1973.

A 46-yr-old woman presented with a 5-month history of pain in the left iliac fossa which had increased in intensity. She had recently become constipated and resorted to laxatives but noticed blood in her stools. Laboratory tests revealed a slight decrease in the RBC, an increase in the WBC, a significant increase in the erythrocyte sedimentation rate, a decrease in plasma albumin with a normal total protein concentration, and traces of albumin, glucose, mucus, and pus in the urine. A barium enema showed stenosis between the sigmoid and rectum which was identified as an adenocarcinoma of the sigmoid by rectosigmoidoscopy. At laparotomy the colon above the tumor had the consistency which is characteristic of ulcerative colitis, so the portion between the middle of the transverse colon and the rectosigmoid junction was removed. Pathological examination of this specimen showed a normal mucosa for about 3 cm above the tumor. Diffuse ulcerative colitis, characterized by total loss of the epithelium from the ulcer surface, was found proximal to the normal mucosa. Perls' test for hemosiderin was positive in the submucosa, indicating that hemorrhagic extravasation had occurred. This is considered to be a manifestation of colitis which results from ischemia and congestion. This conclusion was supported by the antimesenteric, symmetrical distribution of the ulcerative lesions in the colon where blood vessels are exposed to ischemia from increased pressure within the colon.

1358 LARGE BOWEL CANCER IN HAWAIIAN JAPANESE. *(E.)* Haenszel, W.; Berg, J. W.; Segi, M.; Kurihara, M.; Locke, F. B. (Natl. Cancer Inst., Bethesda, Md.). *J. Natl. Cancer Inst.* 51(6):1765-1779, 1973.

A study of 179 Japanese patients with bowel cancer and 357 hospital controls in Hawaii revealed excess risks for persons who regularly ate Western-style meals only. The similarity in findings for Issei and Nisei contrasts with results previously reported for stomach cancer in Issei and Nisei, where the reduced risk among persons regularly eating Western-style meals only was limited to the second-generation Nisei. Bowel cancer was associated with consumption of specific foods. Bowel cancer patients ate meats, legumes, and starches more frequently, with the case-control disparity being less pronounced for individuals consuming starches than for those eating meat and legumes. Beef and string beans were the major contributors to the meat and legume effects. There seemed to be separate effects for beef, string beans, and starches, and the case-control contrasts were strengthened when various combinations of foods were considered. Points of consistency between the Hawaii study and other evidence were noted. The findings on beef had the most immediate relevance. These results may narrow the area of search for etiologic factors and thus assist in planning future research on the complex sequence of events leading to bowel cancer.

1359 DETECTION BY IMMUNOFLUORESCENCE OF CARCINOEMBRYONIC ANTIGEN IN COLONIC CARCINOMA, OTHER MALIGNANT OR BENIGN TUMOURS AND NON-CANCEROUS TISSUES. *(E.)* Bordes, M.; Michiels, R.; Martin, F. (Fac. Med., Dijon, France). *Digestion* 9(2):106-115, 1973.

The indirect fluorescence method has been used to detect and localize carcinoembryonic antigen in specimens of colonic carcinoma, other malignant or benign tumors, and non-cancerous tissues. The antigen was found in 39 of 41 specimens of colonic or rectal adenocarcinomas with a characteristic location at the apical pole of the cancerous cells lining the lumen of the glands. Carcinoembryonic antigen was present in 2 metastases of colonic adenocarcinoma, 1 in the liver and 1 in abdominal lymph nodes. Both cases showed the characteristic linear pattern of the primary tumor. The antigen was not detected in 2 samples of anaplastic colonic carcinomas. Furthermore, carcinoembryonic antigen was occasionally found in some other digestive or nondigestive carcinomas, including 3 located in the stomach. It was also present in 19 benign colorectal polyps examined and in the majority of 85 morphologically non-malignant colonic glands obained from specimens excised for cancerous or non-ancerous diseases. The identity of carcinoembryonic ntigen in non-cancerous adult colon was established y its characteristic apical localization and by isappearance of fluorescence after absorption of he antiserum by a weak concentration of purified arcinoembryonic antigen. It is suggested that the resence of this antigen in adult non-malignant colon ay explain its increase in the serum of some patients ith ulcerative colitis or Crohn's disease.

360 DISTURBANCE OF CELL-MEDIATED IMMUNITY IN PATIENTS WITH CARCINOMA OF COLON AND REC-UM.

(E.) Manousos, O. N.; Economidou, J.; Path-uli, C.; Merikas, G. (Hippokration Gen. Hosp., thens, Greece). *Gut* 14(9):739-742, 1973.

he cellular immune mechanisms of 20 patients (14 ales and 6 females, aged 33-75 yr) with histologic-lly verified adenocarcinoma of colon or rectum were valuated by studying the lymphocyte response to HA stimulation. In each patient this response was tudied in the presence of his own serum and in that f serum from a normal control of the same blood roup. The degree of basic transformation was ssessed by studying the morphology of the cells nd the incorporation of H^3 thymidine into DNA by toradiography. The highest degree of blastic ansformation occurred in lymphocytes of normal sub-ects cultured in the presence of their own serum. he smallest, occurred in cultures of lymphocytes cancer patients cultured in their own serum. Up-ke of H^3 thymidine followed a similar pattern. ntrol lymphocytes showed higher degrees of trans-rmation when cultured with their serum than when rum from cancer patients was present. The degree lymphocyte transformation from cancer patients d not alter significantly whether cultured in their n serum or the serum from healthy controls. Meta-atic cancer was present in 14 of the 20 cases and 9 of these 14 the degree of blastic transformation s above 60%, and it was below 40% in only 3 of the . These results indicate that lymphocytes of can-r patients in their natural environment show a de-eased response to the mitogenic factor PHA. The ppression of normal lymphocytes by the serum of ncer patients supports the theory that an agent sponsible for the decreased transformation resides the serum of the cancer patient. However, the ck of significant improvement in the degree of ansformation when lymphocytes from cancer patients re cultured in serum from controls suggests that ere must also be an inherent defect in the lympho-tes.

51 SODIUM CONSERVATION AFTER TOTAL OR SUB-TOTAL COLONIC RESECTION IN CHILDREN.

(E.) cour, C.; Millot, M.; Balsan, S. (Childrens Hosp., ris, France). *Scand. J. Gastroenterol.* 3):743-750, 1973.

ume of stools, and urine, fecal and urinary ex-etion of sodium, and potassium and urinary excre-n of tetrahydroaldosterone were analyzed in 6 ants (aged 13 to 15 months) and 2 children (aged nd 6 yr) with ileostomies or colostomies. The study was performed using balance techniques. The sole variable was a stepwise reduction of sodium intake, every 6 days. In the absence of the colon, adaptation of the small intestine to sodium restriction was manifested by a decrease in mean fecal sodium concentration and excretion. This phenomenon occurred against a concentration gradient rising from 10 to 80 mEq/l. It seems likely that this enhanced sodium transport was accompanied by a water flux, indirectly demonstrated by reduction of stool volume and by a simultaneous increase of urine flow. During this process, the luminal content remained iso-osmotic because of a significant rise in fecal potassium concentration. A simultaneous rise in the urinary excretion of tetrahydroaldosterone suggests that aldosterone may play a part in the control of sodium conservation at the level of the small intestine. However, symptoms of depletion appear if the intake is reduced to 1 mEq/kg/24 hr, indicating that ileal conservation of sodium is quite limited. When a colonic segment was preserved, sodium balance remained normal even when intake was reduced to 0.3 mEq/kg/24 hr over 6 days. The prevention of fluid and electrolyte depletion in children without a functional colon can be avoided provided a few rules are followed. Survey of such patients should include weight measurements, serum sodium concentration, and 24-hr urinary sodium excretion. In this series a water intake of 150 to 250 ml/kg/24 hr and a sodium intake of 6 to 10 mEq/kg/24 hr permitted satisfactory electrolyte balance without secondary hyperaldosteronism. Maintenance of natriuresis at a level not below 3 mEq/kg/24 hr will avoid accidental sodium and water depletion and cause secretion of aldosterone to remain in normal limits.

1362 LINCOMYCIN AS A CAUSE OF PSEUDOMEMBRANOUS COLITIS.

(E.) Scott, A. J.; Nicholson, G. I.; Kerr, A. R. (Auckland Hosp., New Zealand). *Lancet* (7840):1232-1234, 1973.

Pseudomembranous colitis was studied in 8 patients (6 males and 2 females, aged 21-67 yr). In 7 cases the administration of lincomycin preceded the illness. Of these 7, 3 patients died. An association between pseudomembranous colitis and lincomycin is supported by the frequency with which the disease has been diagnosed since the widespread introduction of the drug. This association also illustrates the role of a disturbance of gut flora in the pathogenesis of some forms of pseudomembranous colitis. It is suggested that lincomycin be used with caution, and only for serious infections such as staphylococcal osteomyelitis and anaerobic infections involving *Bacteroides* spp. If the antibiotic effect of lincomycin is causing the colitis to develop, then similar results must be anticipated with use of the related drug, clindamycin.

1363 INHIBITION OF LEUCOCYTE MIGRATION BY TUMOUR-ASSOCIATED ANTIGENS OF THE COLON AND RECTUM.

(E.) Guillou, P. J.; Giles, G. R. (Leeds Univ. Hosp., England). *Gut* 14(9):733-738, 1973.

The test of leucocyte migration inhibition has been used to detect lymphocyte sensitization to tumor-associated antigens of the colon and rectum. Samples of rectal or colonic adenocarcinomata were obtained from fresh operative specimens, pooled, homogenized, and extracted with perchloric acid. Normal mucosa from the same resected specimens was obtained at least 10 cm away from the tumor site and subjected to the same procedure as the tumor tissue. Following ultracentrifugation and dialysis, the supernatants were lyophilized and the protein content was estimated. Antisera to tumor tissue extract and normal colonic mucosal extract were raised in rabbits and the presence of tumor-associated antigens was demonstrated by the technique of Ouchterlony double-diffusion in Noble agar. Immunodiffusion procedures were performed on each sample of antigen to be certain of continued isolation of antigen from each pool of tumor obtained. The circulating lymphocytes of 22 patients (aged 46-84 yr) suffering from colorectal adenocarcinomata of various stages have been examined and compared with the results obtained for identical studies performed on the peripheral lymphocytes of 15 control subjects. Distant metastases was noted in 13 patients, nodal involvement only in 8, and in 1 case the tumor had only penetrated the muscle coat. Sensitization of lymphocytes to tumor antigen was demonstrated in 15 of the 22 patients when culture was performed in homologous AB serum. Of these 15, only 6 showed inhibition of leucocyte migration in the presence of tumor extract when culture was performed in autologous serum. These observations suggest that factors exist in the serum of such patients which prevent the expression of cellular immunity to tumor antigens.

1364 A RAT MODEL FOR STUDYING COLONIC CANCER: EFFECT OF CHOLESTYRAMINE ON INDUCED TUMORS.

(E.) Nigro, N. D.; Bhadrachari, N.; Chomchai, C. (Dept. Surg., Wayne State Univ., Detroit, Mich.). *Dis. Colon Rectum* 16(6):438-443, 1973.

The effectiveness of dimethylhydrazine, azoxymethane, and methylazoxymethanol in producing malignant tumors in the large intestine of male Sprague-Dawley rats and methods of improving the yield of such tumors was investigated. A group of 24 rats received dimethylhydrazine (15 mg/kg, s.c./week). A second group of 24 received azoxymethane (8 mg/kg, s.c./week). Of the dimethylhydrazine group, 20 rats developed a total of 91 intestinal tumors. All azoxymethane rats developed tumors totalling 131. With dimethylhydrazine there were about the same number of lesions in the small as in the large intestine. A striking preponderance of tumors occurred in the proximal half of each segment of the intestinal tract with either carcinogen. At least 75% of all lesions were polypoid; the remaining, sessile. Abdominal carcinomatosis with ascites occurred in 15% of all rats with tumors. In a second experiment 10 rats received dimethylhydrazine (18 mg/kg), 10 received azomethane (8 mg/kg), and 10 received methylazoxymethanol (6 mg/kg), s.c./week. Only 60% of the rats receiving methylazoxymethanol developed tumors. A second group of 30 rats was similarly treated with the addition of cholestyramine in the amount of 2% added to their diet. In the 10 rats fed dimethylhydrazine, 48 tumors developed; cholestyramine in their diet increased the yield to 76, with the increase occurring largely in the large intestine, especially the distal half. Cholestyramine increased the tumor yield from 68 to 135 in azoxymethane-fed rats and from 14 to 40 in rats receiving methylazoxymethanol. Tumors in cholestyramine-fed rats were larger and the vast majority were sessile, appearing more like human colonic cancer. Rats receiving 2% cholestyramine suffered moderate but not incapacitating steatorrhea. It is concluded that the rat receiving azoxymethane, s.c., at weekly intervals while on a 2% cholestyramine diet is an excellent experimental model for studies of human colonic cancer.

1365 PREOPERATIVE PREPARATION OF THE COLON WITH AN ELEMENTAL DIET.

(E.) Glotzer, D. J.; Boyle, P. L.; Silen, W. (Harvard Med. Sch., Boston, Mass.). *Surgery* 74(5):703-707, 1973.

Vivonex was used in preparation of the colon for operation in 9 patients with particular attention given to its effect on fecal flora. The patients were scheduled to undergo colonic operations for lesions requiring resection and anastomosis or combined abdominal perineal resection. There was a progressive reduction in the dry weight of the stools and preparation was judged satisfactory to excellent in each instance by the operating surgeons. However, there was no change in the types or levels of aerobic or anaerobic fecal bacteria during the period of the study. The pH of the stools of these patients was measured, suspecting that acidification of the stool might result in reduction of fecal flora, but the pH remained stable. Thus results of this study indicated that the diet has merit as an aid in mechanical preparation of the colon while presumably maintaining nutrition, but does not, by itself, reduce or simplify the fecal bacteria.

1366 MUCOSAL HYPERPLASIA, MUCINOUS CYSTADENOMA, AND MUCINOUS CYSTADENOCARCINOMA OF THE APPENDIX. A RE-EVALUATION OF APPENDICEAL "MUCOCELE".

(E.) Higa, E.; Rosai, J.; Pizzimbono, C. A., Wise, L. (Barnes Hosp., St. Louis, Mo.). *Cancer* 32(6):1525-1541, 1973.

Appendiceal lesions (73) fulfilling the criteria of so-called mucocele were evaluated and classified as 1 of 3 distinct clinicopathologic entities: focal or diffuse mucosal hyperplasia, mucinous cystadenoma, or mucinous cystadenocarcinoma. The microscopic pattern in the 18 cases of focal or diffuse mucosal hyperplasia with no epithelial atypia and mild distention of the lumen is highly reminiscent of the colonic hyperplastic polyp. This is a benign lesion, almost always a pathologic finding in appendices removed incidentally. Of the 18 cases, 5 were associated with adenocarcinoma of the large bowel, and 1 with ovarian mucinous cystoma. The 46 cases of mucinous cystadenoma exhibited some degree of epithelial atypia and marked distention of the lumen. Of these 46, 4 were associated with ovarian mucinous cystoma and 9 with adenocarcinoma of the large bowel. In 10 cases, variable amounts of a cellular mucus were present in the periappendiceal region and occasionally free in the peritoneal cavity. In 3 of these cases, the mucus probably originated from

coexistent ovarian tumor. Of the followed patients,
one died as a consequence of appendiceal cystadenoma.
imple excision of the lesion was curative in every
ase. The 9 cases of mucinous cystadenocarcinoma
ere distinguished from the previous 46 cases by the
resence of stromal invasion by glands and/or epi-
helial cells in the peritoneal implants. Peritoneal
nvolvement (*pseudomyxoma peritonei*) was present in
In 2 others the lesion was limited to the append-
, and in the remainder there was direct extension
nto the urinary bladder. Of the 6 patients with
eritoneal extension, 4 died as a result of the di-
ease 2-11 yr after the original surgery, 1 was lost
follow-up, and the 6th is a recent observation.
e 2 patients with localized tumor were alive and
ll 2 and 19 yr after treatment. The patient with
rect extension into the urinary bladder was alive
d well 7 yr after an anterior pelvic exenteration.
the basis of these findings, it is suggested that
st instances of so-called mucocele be regarded as
cinous neoplasms, analogous in many aspects to epi-
elial tumors of the colon, with peculiarities prob-
ly due to the anatomical characteristics of the
gan in which they arise.

67 THE VALUE OF BARIUM-ENEMA STUDIES IN PATIENTS WITH CARCINOMA OF THE RECTUM.

.) Jensen, H. E.; Balslev, I.; Kragelund, E.;
elsen, J. (Kommune Hosp., Copenhagen, Denmark).
s. Colon Rectum 16(6):482-484, 1973.

rium-enema studies of the colon undertaken in
007 patients with carcinoma of the rectum failed
demonstrate the rectal tumor in 16% of the cases,
d failed to demonstrate coincidental tumors of the
lon in 63% of patients with such tumors. Addi-
onally there was a 0.25% incidence of false-positive
ndings in the colon. Barium studies must be under-
ken in cases of coincidental ulcerative colitis
familial polyposis to determine the extent of
ese conditions. However, it is suggested that the
rium-enema studies of the colon in patients with
rcinoma of the rectum confirmed by palpation or
octoscopy need no longer be performed. Thus, the
rgeon is very aware of the importance of his pre-
erative palpation, which has proved to be very
ch more reliable for detecting coincidental tumors
the colon than preoperative barium-enema studies.

68 AN ELECTRON MICROSCOPE STUDY OF THE AUERBACH'S PLEXUS AND DETERMINATION OF SUB-
ANCE P OF THE COLON IN HIRSCHSPRUNG'S DISEASE.

) Tafuri, W. L.; Maria, T. A.; Pittella, J. E.
Bogliolo, L.; Hial, W.; Diniz, C. R. (Fac. de
. U.F.M.G., Belo Horizonte, Brazil). *Virchows
h. (Pathol. Anat.)* 362(1):41-50, 1974.

electron microscopic study of the Auerbach's
xus and determination of substance P of the
on was presented for 3 cases of Hirschsprung's
ease. In the 3 cases studied, isolated Auer-
h's ganglia showed, under optical microscopy,
be normal and displayed voluminous neurons and
ve fibers with enlarged caliber. The lesions
t frequently observed in the neuron body were:
tial, focal or, diffuse tigrolysis; tumefaction, partial or total cristolysis, and lysis of the mitochondria matrix; enlargement of the cisternae of the endoplasmic reticulum; and presence of numerous liposomes and lysosomes and eventual loss of the whole architecture. All nerve fibers were unmyelinated. They were always filled with vesicular components, dense granular vesicles, as well as intermediary and clear ones. No great alterations were observed in the Schwann cells. Their cytoplasm looked developed and presented well-individualized gliofilaments. The extrinsic nerve fibers of the distal portion were seen in bundles, the fibers were disorderly, followed various directions and showed an increase in thickness and enveloped in a sheath of connective tissue. There was a significant increase of substance P in the dilated part of the colon as compared with that in the narrowed segment. It is concluded that substance P, which is always found in larger amounts in the ganglionic portion of the colon (than in the aganglionic one), may be related with the granular vesicles of Auerbach's plexus.

1369 THE BEHAVIOUR OF CARCINOMA OF THE LARGE BOWEL IN MAN FOLLOWING TRANSPLANTATION INTO IMMUNE DEPRIVED MICE.

(E.) Cobb, L. M. (Roy. Cancer Hosp., London, England). *Brit. J. Cancer* 28(5):400-411, 1973.

The growth of carcinoma of the human large bowel was studied in the first 2 passages in immune deprived mice. Male and female CBA/lac mice were thymectomized at 4 weeks of age and were given 900 rad whole body irradiation at 8 weeks. Irradiation was given at 60 rad/min using a 220 kV x-ray machine h.v.l. 0.4 mm^3, focal distance 100 cm. This dose of radiation would have been lethal without a bone marrow graft. Within 6 hr of irradiation, each animal received 5×10^6 syngeneic femoral bone marrow cells, i.v. The animals received the tumor graft between 2 and 4 weeks after irradiation. Tumors were obtained from large bowel resections on 3 people. A strong histological similarity between the patient's tumor and that which grew in the mice 2-8 months after implantation was noted. One dissimilarity was a higher mitotic index in some of the tumors in the immune deprived animals. In the second passage of bowel tumors, cells were implanted into groups of 8-10 animals in the following sites: subcutaneous, intramuscular, intravenous, intrahepatic, intraperitoneal, and intrathoracic. Tumor growth was observed from all 3 tumors when they were implanted subcutaneously, intramuscularly, intraperitoneally, and intrathoracically. Infiltration of muscle by tumor was a frequent finding. Lung metastases developed after injection of cells in 1 of 3 tumors. In none did growth follow injection of cells directly into the substance of the liver. Spontaneous metastasis was not observed.

1370 GARDNER'S SYNDROME.

(E.) Alm, T.; Dencker, H.; Lunderquist, A.; Mark, J.; Mitelman, F.; Norryd, C.; Tranberg, K. (Dept. Surg., Univ. Lund, Sweden). *Acta Chir. Scand.* 139(7):660-665, 1973.

Seven cases of Gardner's syndrome in one family are presented and discussed. Among these, 2 children, 7 and 8 years old, were found to be affected. The extracolonic manifestations were roentgenographically demonstrated small osteomas in 3 cases, and a desmoid arising *de novo* in one. Five patients had not sought medical advice, but their names were on a central register for control of polyposis families and they were invited to the hospital for an examination. So far, 4 of the patients have undergone colectomy and 3 had multifocal carcinoma. Relatives of patients with Gardner's syndrome and familial colonic polyposis should be subjected to roentgen examination of the colon. Skeletal X-rays should also be performed and the patients carefully examined for subcutaneous tumors since growths in these sites may be the first objective signs of Gardner's syndrome.

1371 THE ACTIVITY OF PHOSPHOFRUCTOKINASE AND LACTATE DEHYDROGENASE IN CANCER OF THE COLON AND RECTUM AND THE EFFECT OF IODINE ON THE NORMAL MUCOSA. *(E.)* Briand, P.; Fischerman, K. (Rigshosp., Copenhagen, Denmark). *Acta Chir. Scand.* 139(7):666-670, 1973.

Phosphofructokinase and lactate dehydrogenase activities were assayed in malignant tumors of the colon or rectum of 15 patients. The average tumor value of phosphofructokinase was about 50% higher, and of lactate dehydrogenase, about 100% higher than in the histologically noninvolved mucous membrane of the same organ. Based on paired observations, these increases are highly significant. In a few cases, the enzyme values of adjacent noninvolved tissue were at tumor level. It is suggested that this indicates very early neoplastic (premalignant) changes. Application of relatively high iodine concentrations (but not high enough to interfere with the healing processes in test animals) to the colon mucosa of man, pig, and dog markedly decreased the in vitro tissue enzyme activity. It is concluded that the tumor cells dislodged to the iodine-treated areas may be growth-inhibited.

1372 COLON PERFORATIONS ASSOCIATED WITH STEROID THERAPY. *(E.)* Sterioff, S.; Orringer, M. B.; Cameron, J. L. (Baltimore City Hosp., Md.). *Surgery* 75(1):56-58, 1974.

Colon perforations associated with steroid therapy were studied in 10 patients. All patients were on oral prednisone for a variety of underlying illnesses. The dose ranged from 10 to 80 mg/day with a mean of 20 mg/day. The duration of medication ranged from 5 days to 6 yr with a mean of 10 months. The underlying diseases were: disseminated lupus erythematosis; postrenal transplant; postbone-marrow transplant for acute monocytic leukemia; emphysema and bronchial asthma; and rheumatoid arthritis. In 8 patients there was some delay in the diagnosis of the colon perforation. Fever and abdominal tenderness were present in almost all patients. Leukocytosis and rebound tenderness were often absent. In only 2 patients was an unequivocal diagnosis made of a perforated viscus by the consulting surgeon on initial physical examination. Eight patients had perforated diverticula, all in the rectosigmoid. Two patients had a vasculitis involving the transverse colon with necrosis, ulceration, and perforation. Only 3 of the 10 patients survived. All 3 survivors had walled off the perforation prior to presentation and a well-defined abscess was demonstrated by barium enema. It is concluded that clinical recognition will be aided by remembering that in any steroid-treated patient with fever and abdominal symptoms, the colon should be suspect.

LARGE INTESTINE

Ulcerative Colitis

3 ELECTRICAL POTENTIAL DIFFERENCE AND SODIUM
AND POTASSIUM FLUXES ACROSS RECTAL MUCOSA
ULCERATIVE COLITIS. *(E.)* Edmonds, C. J.; Pil-
r, D. (Univ. Coll. Hosp. Med. Sch., London,
land). *Gut* 14(10):784-789, 1973.

transmucosal electrical potential difference and
sodium and potassium flux rates have been mea-
ed in the rectum and distal sigmoid colon of 8
ients with ulcerative colitis and compared with
surements made in individuals having normal bowel
ction. In active colitis, a very low transmucosal
ential difference was found and was associated
h loss of the characteristic ability of the mucosa
absorb sodium against considerable electrochemical
dients; a marked increase in the plasma-to-lumen
ium flux rate, suggesting increased leakiness of
mucosa; and loss of the active sodium absorption
hanism. In resolving colitis, the potential dif-
ence was higher and all these changes of sodium
nsport tended to return toward normal. With full recovery, epithelial function was normal to the present tests. Potassium secretion rate showed little difference at various stages of the disease, but the nearly normal secretion of potassium in ulcerative colitis when the potential difference was low suggested that potassium loss to the lumen was excessive. Mucus collected from patients with ulcerative colitis had a relatively high sodium and potassium content. Measurement of potential difference and absorption by using a dialysis tube offers a simple means of rapid assessment of mucosal functional integrity.

1394 LYMPHOBLASTIC RESPONSE TO AUTOLOGOUS COLON EPITHELIAL CELLS IN ULCERATIVE COLITIS IN VITRO. *(E.)* Hunt, P. S.; Trotter, S. (Dept. Surg., Monash Univ., Melbourne, Australia). *Gut* 14(11):875-879, 1973.

The blastic transformation *in vitro* of peripheral blood lymphocytes was measured by the 72 hr uptake of ^{3}H-6-thymidine in 23 patients with mucosal ulcerative colitis, 3 with acute Crohn's colitis with rectal involvement, and 7 normal subjects, all aged 19-62 yr. The 23 patients with ulcerative colitis were divided into 3 groups graded according to severity as acute, severe (7); active, chronic (9); and quiescent disease (7). In the control cultures of lymphocytes without any added potential stimulant the uptake of ^{3}H-6-thymidine in the clinical subgroup of 7 patients with acute, severe ulcerative colitis was significantly greater than in 7 normal subjects. This contrasted with a reduced uptake of tritiated thymidine by lymphocytes from the acute severe colitis patients when compared with 7 normal subjects after stimulation with phytohemagglutinin-P. In further duplicate cultures of lymphocytes specifically stimulated by an equal number of viable autologous rectal epithelial cells, the uptake of tritiated thymidine was significantly greater in 7 acute severe colitis patients when compared with 7 normal subjects. The results in 3 patients with acute Crohn's colitis with rectal involvement showed no such evidence of lymphocyte sensitivity to autologous rectal epithelial cells and their uptake of tritiated thymidine was normal. Results obtained in the unstimulated and epithelial cell stimulant cultures gave evidence that the degree of lymphoblastic transformation was related to the clinical severity of ulcerative colitis. The uptake of ^{3}H-6-thymidine was directly related to the clinical severity of ulcerative colitis in the 3 subgroups studied. In addition, of the 7 patients with acute severe colitis, 4 were studied later in clinical remission and had significantly reduced uptake of tritiated thymidine in response to autologous rectal epithelial cells.

PANCREAS

1399 RADIATION THERAPY IN THE TREATMENT OF IRRESECTABLE ADENOCARCINOMA OF THE PANCREAS. *(E.)* Haslam, J. B.; Cavanaugh, P. J.; Stroup, S. L. (Duke Univ. Med. Ctr., Durham, N. C.). *Cancer* 32(6):1341-1345, 1973.

Irresectable adenocarcinoma of the pancreas in 29 patients (18 males and 11 females, aged 40-77 yr) was treated with radiotherapy between the years 1961 and 1971. In 6 patients the tumor was widespread. Regional malignancy occurred in 23 patients and these were treated with curative intent. Some patients received adjunctive chemotherapy with 5-fluorouracil (13 patients), cyclophosphamide (1), or amethopterin (1). The radiotherapeutic technique used in 23 cases when cure was thought possible consisted of 6000 R calculated at the frontal midplane (anterior-posterior diameter) of the pancreas region, using Cobalt 60, in 10 weeks elapsed time. Three series of 2000 R in 10 fractions (2 weeks) were given, spaced by intervals of 2 weeks. The crude survival figure was 21% at 2 1/2 yr following diagnosis for all 29 patients. The morbidity of treatment was low; palliative results were encouraging. These results suggest an advantage of high-dose split-course megavoltage irradiation in localized irresectable adenocarcinoma of the pancreas. It is felt that patients unable to complete the radiotherapy course were victims of unyielding tumor rather than adverse effects of treatment.

1400 INTRAJEJUNAL ADMINISTRATION OF AN ELEMENTAL DIET AT NEUTRAL pH AVOIDS PANCREATIC STIMULATION. STUDIES IN DOG AND MAN. *(E.)* Ragins, H.; Levenson, S. M.; Signer, R.; Stamford, W.; Seifter, E. (Albert Einstein Coll., Med., Bronx, N.Y.). *Am. J. Surg.* 127(4):606-614, 1973.

An elemental diet (Vivonex 100) stimulated pancreatic secretion when instilled into the

tomach of dogs. When Vivonex 100 at pH 5.4
as perfused through a hir-Vella loop, pan-
reatic secretion was not stimulated signifi-
antly, although the bicarbonate output did
ncrease significantly. A mixture of essential
nd nonessential amino acids and a mixture of
henylalanine, leucine, and tryptophan, when
erfused through a Thiry-Vella loop at pH
.0 and in the concentration present in Vivonex
00, caused minimal stimulation of pancreatic
ecretion. When the same amino acid mixtures
cidified to a pH of 3.5 were perfused through
Thiry-Vella loop, stong pancreatic secretion
ccurred. Perfusion of hypertonic glucose
olution (22.6%) in a Thiry-Vella loop inhibited
rotein and bicarbonate output from the pancreas.
hen 22.6% glucose solution was introduced
nto the stomach, pancreatic secretion was stimu-
ated. When amino acid mixtures in the con-
entration present in Vivonex 100 were instilled
nto the stomach, strong stimulation of pan-
reatic secretion resulted. These results
phasize the importance of bypassing the stomach
d minimizing acid secretion to keep the pan-
reas at rest. Measurements of net absorption
om the Thiry-Villa loop suggest that sodium
loride enhances glucose absorption. Hyper-
nic glucose appears to inhibit amino acid
sorption from a jejunal loop. It is suggested
at separation of the amino acids and the
ucose for intrajejunal feedings may improve
e absorption of amino acids. This may be of
rticular importance in feeding elemental diets
patients with the short bowel syndrome.

01 ECHOGRAPHY B COMBINED WITH SCINTIGRAPHY IN THE DIAGNOSIS OF PANCREATIC DISEASE.
r.) Murat, J.; Chenille, E.; Floyrac, G.; Garnier,
; Crassas, Y.; Planiol, T.; Aron, E. (Bretonneau
iv. Hosp. Ctr., Tours, France). *Arch. Fr. Mal.*
p. Dig. 62(6):449-463, 1973.

e results of pancreatic echography and differential
ncreatic and hepatic scintigraphy were compared
th those of clinical and conventional radiological
thods (hypotonic duodenography, intravenous cholan-
ography, and celiac arteriography) in 15 patients
men and 6 women, aged 37-82 yr) with symptoms
ferable to the pancreas. Jaundice was present in
cases. Pancreatic disease was confirmed at sur-
ry in 10 patients and consisted of pancreatitis
cases) and cancer of the pancreas (2 cases). The remaining 5 patients had gallbladder cancer (1), tumor of the ampulla of Vater (1), cholelithiasis with an abscess of the gallbladder (1), celiac disease (1), and a juxtapancreatic calcifying adenopathy (1). By combining echography and scintigraphy, a correct diagnosis of the state of the pancreas was obtained in 14 of the 15 patients. The clinical diagnosis was incorrect in 6 cases, and conventional radiological diagnosis was incorrect in 7. It is recommended that a combination of echography and scintigraphy be used to confirm that the pancreas is normal, to confirm a diagnosis of chronic or acute pancreatitis, and to demonstrate the presence of cancer of the pancreas. This method is also of value in diagnosing small pseudocysts although the conventional radiological methods usually suffice in the diagnosis of large pseudocysts.

PANCREAS

Pancreatitis

06 ANTIBODY RESPONSE IN PATIENTS WITH ACUTE PANCREATITIS TO MYCOPLASMA PNEUMONIAE.
) Leinikki, P.; Pantzar, P.; Tykka, H. (Dept.
ol., Univ. Helsinki, Finland). *Scand. J. Gastro-*
erol. 8(7):631-635, 1973.

Paired sera from 56 patients with acute pancreatitis were studied to detect signs of viral or mycoplasma infection during the illness. In 18 patients a significant increase in titres with chloroform-extracted Mycoplasma pneumonia antigen could be demonstrated. In 28 patients constant or negative titres were observed, and 10 had variable results from test to test. The clinical picture of pancreatitis was similar in both mycoplasma pneumonia-positive and negative groups. The absence of epidemiological fluctuation in the incidence of acute pancreatitis, and the absence of respiratory illness in these patients rebut the hypothesis that mycoplasma pneumonia antigen would play an essential role in the disease. The lack of very high complement fixation-titres and the variable behavior in some of the sera would rather suggest an antigenic stimulus by some related mycoplasma or tissue component of pancreatic origin.

1407 ACUTE PANCREATITIS IN PATIENTS WITH ACUTE HEPATIC FAILURE. *(E.)* Ham, J. M.; Fitzpatrick, P. (Prince Henry Hosp., Little Bay, Australia). *Am. J. Dig. Dis.* 18(12):1079-1084, 1973.

The incidence of acute pancreatitis was studied in 42 patients with acute liver failure, the majority due to short-incubation hepatitis. The diagnosis of pancreatitis was based on autopsy findings, and classified as severe, moderate, or mild. Fourteen patients (33%) had evidence of pancreatitis: severe in 4, moderate in 5, and mild in 5. It is suggested that this pancreatitis was due either to the virus causing infectious hepatitis or to the blood coagulation changes accompanying acute liver failure. Acute pancreatitis should be considered as one of the possible causes of sudden clinical deterioration in patients with acute liver failure.

1408 SERUM IMMUNOGLOBULINS IN CALCIFIC PANCREATITIS. *(E.)* Bank, S.; Novis, B. H.; Petersen, E.; Dowdle, E.; Marks, I. N. (Groote Schuur Hosp., Cape Town, South Africa). *Gut* 14(9):723-725, 1973.

Serum immunoglobulin concentrations were measured in 40 patients with calcific pancreatitis. A significant elevation was found of the mean serum IgA and IgG concentration when compared with a control group. The IgA was raised in 50% and the IgG in 27.5% when the individual results were assessed. The IgA did not appear to be of the secretory type. The raised immunoglobulin levels appeared to be related to the pancreatic disease and not to the presence of extrapancreatic infection, activity of the disease, or the presence of pancreatic diabetes or steatorrhoea. It is conceivable that the elevated IgA and IgG levels reflect, in a poorly understood, nonspecific manner, the presence of chronic inflammation in the pancreas. The high immunoglobulin levels may be related to autoimmune processes in the pancreas once the disease is established and may contribute to the progressive nature of the disease.

1409 THE DIAGNOSTIC VALUE OF ORAL GLUCOSE TOLERANCE TEST AND COMBINED B-CELL STIMULATION IN CHRONIC PANCREATITIS. *(E.)* Grabner, W.; Phillip, J.; Strigl, P. (Dept. Med., Univ. of Erlangen/Nurenberg, West Germany). *Am. J. Dig. Dis.* 18(12):1055-1060, 1973.

The secretory capacity of the B-cells in 40 patients with chronic or chronic relapsing pancreatitis was examined by means of the oral glucose tolerance test (100 g of glucose, orally) and combined stimulation (100 g of glucose, orally, 1 mg of glucagon, and 0.5 g of tolbutamide intravenously. The patients with chronic or chronic relapsing pancreatitis showe distinctly decreased insulin values. The simultaneously determined blood glucose concentrations were increased at every point of the test in all patients The immunologically measurable insulin was significantly reduced, when compared with the controls. The maximal insulin differences and the insulinogeni index (35-minute value) of the combined stimulation method were most satisfactory for the diagnosis of the secretory B-cell insufficiency. In addition to these parameters, the constancy of insulin levels i the period between 35 and 60 minutes indicated a dysfunction of the endocrine pancreas.

1410 PLASMA LEVELS OF ELASTASE, TRYPSIN AND THEIR INHIBITORS IN BILE INDUCED PANCREATITIS IN THE DOG. *(E.)* Satake, K.; Reichman, J.; Carballo, J.; Appert, H. E.; Howard, J. M. (Hahnemann Med. Coll., Philadelphia, Pa.). *Ann. Surg.* 179(1):58-61, 1974.

The levels of several pancreatic enzymes were measured serially in the plasma and lymph of 15 mongrel dogs for 5 hr following bile induced-pancreatitis. Plasma amylase, lipase, trypsinogen, and trypsin levels rose during the 5-hr-period after pancreatitis. Plasma total elastase levels decreased to les than half of control values. Free elastase levels in the femoral and portal veins rose slightly in the 1st hr after which they returned to normal. Th decrease in elastase may be partially explained by a decreased liberation of unbound elastase by the pancreas. Since the portal vein levels of elastase inhibitor increased, increased output of elastase inhibitor may also partially account for the drop i circulating elastase observed following the inducti of pancreatitis. In contrast to elastase inhibitor trypsin inhibitor decreased in the portal vein whil the trypsin inhibitor in the systemic circulation appeared to increase slightly. These differences suggest that trypsin inhibitor is produced in the liver and elastase inhibitor by the pancreas or som other extrahepatic abdominal organ.

1411 UPTAKE AND INCORPORATION OF AMINO ACIDS BY RAT PANCREAS IN VITRO DURING ACUTE, EXPERIMENTAL PANCREATITIS. *(E.)* Machovich, R.; Szikla, K. (Inst. Med. Chem., Semmelweis Univ. of Med., Budapest, Hungary). *Enzyme* 14(6):372-377, 1973.

The uptake of amino acids by pancreatic cells *in vitro* and their incorporation into proteins were examined 24 hr after induction of acute pancreatiti in male CFE rats. Acute pancreatitis was induced by injecting deoxycholate or physiological saline

olution into the ductus pancreaticus. The pancreas
as removed and minced 24 hr after treatment of ani-
als. Uptake of ^{14}C-valine at 37 C was 505 dpm/mg
ntracellular water in the deoxycholate-treated sam-
les, 543 in the normal samples, and 640 after physio-
ogical saline. The uptake at 0 C was about 50% of
hat at 37 C. Deoxycholate treatment decreased the
apacity for incorporation at 37 C from 63,800 to
,193 dpm/mg protein; saline treatment decreased it
omewhat, to 21,366 dpm/mg protein. Incubation at
C resulted in essentially no incorporation. After
0 min incubation at 37 C, the size of the valine
ool in the normal and in the damaged pancreas was
lmost identical. In pancreas treated with deoxy-
holate, the specific activities of lipase and ATPase
ere low 24 hr following the induction of acute pan-
reatitis. The activity of lipase diminishes from
.066 to 0.011 U/mg protein and that of ATPase, from
400 to 1700 cpm/mg protein. The results thus indi-
ate that acute pancreatitis is associated with a
iminished capacity for protein synthesis. This is
aralleled by a decrease in the specific activity of
ipase and ATPase.

412 ON THE LYSOLECITHIN CONTENT OF THE PANCREAS IN EXPERIMENTAL ACUTE PANCREATITIS.
.) Papp, M.; Breuer, J. H.; Nemeth, E. P.; Fodor,
; Folly, G. (Semmelweis Univ. Med. Sch., Budapest,
ungary). *Gastroenterology* 65(5):778-787, 1973.

l the major phospholipid classes were found in
e pancreas, pancreaticoduodenal lymph, and arterial
ood plasma of 31 anesthetized male, mongrel dogs.
e proportion of lysolecithin was significantly
gher in the pancreaticoduodenal lymph than in the
ncreas; however, its concentration was higher in
e pancreas than in the lymph. Retrograde injec-
on of 3% sodium taurocholate failed to increase
ther the concentration or the proportion of lyso-
cithin in the dog pancreatic tissue, arterial
ood plasma, pancreaticoduodenal venous plasma,
pancreaticoduodenal lymph 30 or 90 min after
jection, although at 90 min extensive pancreatic
crosis and highly elevated lipase activity were
und in pancreaticoduodenal venous plasma. A
xture of activated pancreatic juice containing
solecithin increased both the concentration and the
oportion of lysolecithin in the dog pancreas and
oduced focal pancreatic necrosis in 90 min. In the pancreas of 39 male albino rats, the retrograde injection of 10 mg of trypsin failed to increase the concentration of lysolecithin 90 min after injection, although it produced acute hemorrhagic pancreatitis. These results cast considerable doubt on the validity of the assumption that lysolecithin formed during the enzymatic hydrolysis of lecithin is responsible for pancreatic injury during the early phases of acute experimental pancreatitis which is induced by either bile salt or trypsin.

LIVER AND BILIARY TRACT

18 BSP IN THE STUDY OF LIVER FUNCTION DURING PREGNANCY. (PRELIMINARY REPORT). *(Sp.)*
ilicoff, R.; Perelstein, G. I.; Gilardoni, A.;
hon, M. (U.A.M.I., Rivadavia, Argentina). *Acta
stroenterol. Latinoam.* 5(2):65-69, 1973.

P clearance, storage, and maximal transport were
termined on 7 pregnant and 12 nonpregnant women with no evidence of hepatobiliary disease and on 5 pregnant women with pruritis and/or cholestasis. Values for BSP storage were higher and those for maximal transport were lower in normal pregnant women than in nonpregnant controls, but these differences were not statistically significant. An analysis of K_1 and K_2 showed no differences between values for nonpregnant and normal pregnant women.

In pregnant women with pruritis and/or cholestasis significant decreases were found in maximal transport and values for K_1 and K_2. These findings suggest that the uptake and excretion of BSP are impaired in these patients.

1419 HEPATIC GRANULOMATOSIS AND SARCOIDOSIS.

(E.) Israel, H. L.; Goldstein, R. A. (Jefferson Med. Coll., Philadelphia, Pa.). *Ann. Intern. Med.* 79(5):669-678, 1973.

Noncaseating hepatic granulomatosis was present in 30 patients with normal chest roentgenograms. Of these 30, 15 (9 females and 6 males, aged 19-75 yr) had granulomas demonstrated only in the liver, usually by percutaneous biopsies performed due to unexplained fever, fatigue, or abnormal liver function tests. A final diagnosis was possible only in 2 cases, 1 with sarcoidosis and the other with Hodgkin's disease. Most of these 15 recovered spontaneously without treatment. Some had fever persist for many months until corticosteroid therapy was started. Of these 15, 1 died of malignant melanoma and a second of Hodgkin's disease. Kveim tests were negative in 12 of 13 patients so tested. Multisystem granulomatosis was verified in the other 15 patients (8 males and 7 females, aged 13-76 yr). Of these 15, 8 had sarcoidosis and 7, probable sarcoidosis, 1 of whom had Hodgkin's disease. Spontaneous recovery occurred in 2 patients, the other 13 required steroid therapy to control symptoms. Kveim tests were negative in 13 of 14 so tested. All but 2 were tuberculin negative. Granulomas persisted in 1 patient after 18 yr of corticosteroid therapy and after 4 yr of immunosuppressive treatment in another patient. It was concluded that a thorough diagnostic study of patients with hepatic granulomatosis of uncertain cause is necessary. Second-strength tuberculin is reliable in excluding tuberculosis. Trials of antimicrobial therapy are not useful in tuberculin-negative patients. Hodgkin's disease can present a typical sarcoid reaction of the liver, most likely due to concurrent sarcoidosis and lymphoma. Kveim tests are of little value in excluding sarcoidosis. Biopsies from several tissues are needed for accurate diagnosis when the usual thoracic changes are absent.

1420 CIRCULATING TISSUE ANTIGENS. II. STUDIES ON AN ORGAN-SPECIFIC ANTIGEN OF HUMAN LIVER.

(E.) Espinosa, E. (Univ. Louisville Sch. Med., Ky.). *Lab. Invest.* 29(5):556-561, 1973.

A liver-specific antigen detected in serum of certain patients with viral hepatitis was identified in saline extracts of liver tissue from man, rhesus monkey, and dog but was absent in other mammalian species including rodents. Liver-specific antigen was susceptible to digestion by Pronase, was relatively termolabile, was inactivated at acid pH levels, was nonsedimentable at 105,000 x g for 60 min, and was precipitated by 20% ethanol. In immunoelectrophoresis, it had an electrophoretic mobility of serum gamma-globulins. The sedimentation coefficient by sucrose density gradient ultracentrifugation was 6.2S. The molecular radius determined by Sephadex gel filtration was 36.5 A and the diffusion coefficient, 5.7×10^{-7} sq cm/sec. The molecular weight was 82,000 to 93,000, depending on the method used, and the frictional ratio was 1.2. Partial putification from saline extract of human liver was obtained by ethanol precipitation, column chromatography, and gel filtration. Liver-specific antigen has restricted species cross-reactive properties. The relevance of the appearance of this antigen in blood in conditions involving liver damage is currently under study.

1421 PRIMARY HEPATIC TUMORS IN INFANCY AND CHILDHOOD.

(E.) Pollice, L. (Inst. Pathol Anat., Univ. Bari, Italy). *Am. J. Clin. Pathol.* 60:512-521, 1973.

A report of 8 cases involving primary hepatic tumors in infancy and childhood is presented. The children ranged in age from 7 weeks to 15 years old. The presenting symptoms included: palpable painful epigastric mass; palpable painful abdominal mass; palpable abdominal mass; abdominal distention and firmness; loss of weight; abdominal distention; and hepatomegaly. The surgical findings revealed that adenomas, teratomas, and hepatoblastomas were present as a single large mass, while hepatocarcinomas and haemangioendotheliomas manifested as numerous nodules scattered throughout the liver. Four of the 8 children died. The microscopic patterns corresponded to the peculiar features of the tumors. Among the laboratory data, it was remarkable that alpha$_1$ fetoglobulin, an immunoglobulin normally present only in fetal life and found in the sera of most adult patients with hepatocarcinoma, was detected in large amounts in the case of trabecular hepatocarcinoma, while it was not found in the embryonal hepatoblastoma. It is concluded that the most common of primary hepatic tumors in infancy and childhood, hepatoblastomas and infantile hemangioendotheliomas, because of their occurrence early in the life, often in association with congenital malformations, result at least partly from genetic factors and should be included among the dysembryogenetic tumors.

1422 HEPATOCELLULAR CARCINOMA PRESENTING WITH PATHOLOGIC FRACTURE DUE TO BONE METASTASES

(E.) Talerman, A.; Magyar, E. (Inst. of Radiotherap Rotterdam, Netherlands). *Cancer* 32(6):1477-1481, 1973.

Two cases of hepatocellular carcinoma presenting with pathologic fracture due to bone metastases are reported. The patients did not exhibit clinical evidence of liver disease on presentation, and there was no previous history of liver disease. Liver function tests were normal in 1 case, while in the other the only abnormality was a slightly raised alkaline phosphatase. In 1 case the diagnosis was made by needle biopsy of a metastatic bone lesion, and in the other only at autopsy. It is considered

hat hepatocellular carcinoma should be included in
he differential diagnosis of carcinoma metastatic
o bone.

423 VITAMIN E DEFICIENCY IN HUMAN LIVER DISEASE AND ITS RELATION TO HAEMOLYSIS.

E.) Powell, L. W. (Roy. Brisbane Hosp., Australia).
ust. N.Z. J. Med. 3(4):355-360, 1973.

lasma vitamin E levels and *in vitro* and *in vivo*
emolysis were measured in 17 patients with various
orms of liver disease and in 16 control subjects.
itamin E deficiency was demonstrated in patients
ith long-standing obstructive jaundice (presumably
ue to malabsorption from bile salt deficiency) and
as shown to contribute in part to the reduced red
ell survival accompanying this disorder. However,
tamin E deficiency was not the sole cause of the
emolysis since, in contrast to patients with primary
alabsorption, the red cell survival did not return
mpletely to normal following vitamin E administra-
on. Furthermore, in three patients the red cell
rvival was reduced while the plasma vitamin E
vel was within the normal range. Primary hepato-
llular disease without cholestasis was not asso-
ated consistently with vitamin E deficiency and
e red cell survival in these subjects, while fre-
ently abnormal, was not altered by pharmacological
ses of vitamin E. The results indicate that vita-
n E deficiency may result from long-standing ob-
ructive jaundice and that it contributes in part
the reduced red cell survival accompanying this
sorder.

24 SPONTANEOUS RUPTURE OF THE LIVER CAUSED BY HEPATOMAS.

(E.) Hermann, R. E.; David,
E. (Cleveland Clin. Fdn., Ohio). *Surgery*
(5):715-719, 1973.

o cases of spontaneous rupture of the liver, an
common problem, rarely encountered or reported in
e United States are reported. It is caused, in
st cases, by a tumor in the involved hepatic lobe,
st often a hepatocellular carcinoma. One patient,
29-year-old woman, had a hepatocellular carcinoma;
second patient, a 20-year-old woman had a hepato-
llular adenoma. Both patients have had hepatic
ectomies and are alive and well. The incidence,
chanism, and other causes of spontaneous rupture
the liver are reviewed. Hepatic arteriography is
aluable aid in diagnosis and in determining re-
tability. Because of the frequency of hepatoma
the underlying cause of spontaneous rupture of
liver and the difficulty in distinguishing a
ign hepatocellular adenoma from a hepatocellular
cinoma, the recommended treatment for spontaneous
ture of the liver should be as complete a resec-
n of the involved hepatic lobe as possible.

5 GASTRIN IN PORTAL AND PERIPHERAL VENOUS BLOOD AFTER FEEDING IN MAN.

(E.) Dencker,
Hakanson, R.; Liedberg, G.; Norryd, C.; Oscarson,
Rehfeld, J. F.; Stadil, F. (Dept. Surg., Univ.
d, Sweden). *Gut* 14(11):856-860, 1973.

The concentrations of immunoreactive gastrin in serum from portal and peripheral venous blood were determined in 10 patients with indwelling portal catheters before and after feeding. Serum gastrin concentrations were abnormally high in the fasting state in 3 patients. No significant differences were found between the gastrin concentrations in portal and peripheral serum. Feeding induced a rapid increase in serum gastrin in both portal and peripheral blood with a maximum after 15 to 30 minutes, followed by a gradual decrease. Gel filtration studies of serum did not reveal any differences between the gastrin components of portal and peripheral venous serum. Since neither the concentrations of immuno-reactive gastrin nor the four gastrin components differed between portal and peripheral serum it is suggested that the liver is without effect on gastrin metabolism.

1426 ABNORMALITIES IN LIVER FUNCTION TESTS DURING LONG-TERM DIPHENYLHYDANTOIN THERAPY IN EPILEPTIC OUT-PATIENTS.

(E.) Andreasen, P. B.; Lyngbye, J.; Trolle, E. (Univ. Hosp., Copenhagen, Denmark). *Acta Med. Scand.* 194(4):261-264, 1973.

Results in liver function tests were studied in 51 epileptic out-patients on long-term anticonvulsant treatment with diphenylhydantoin (DPH) alone or a combined regimen and compared with a group of 250 control patients. The epileptics had significantly raised serum alkaline phosphatases, serum alanine aminotransferase, and plasma prothrombin time. Serum albumin was significantly decreased, as well as serum calcium and serum bilirubin. In male epileptics significantly raised serum phosphate concentrations were found. There was no significant correlation between the clearance rate of DPH and the liver tests. It is suggested that the inducing effect of DPH and other anticonvulsant drugs may explain the abnormalities in liver function tests and calcium metabolism. The possibility remains, however, that prolonged administration of these drugs to humans may eventually result in liver damage.

1427 SEVERE FAMILIAL INTRAHEPATIC CHOLESTASIS.

(E.) Odievre, M. Gautier, M.; Hadchouel, M.; Alagille, D. (Parrot Hosp., Bicetre, France). *Arch. Dis. Child.* 48(10):806-812, 1973.

Severe familial intrahepatic cholestasis was examined in a series of 5 case studies belonging to 4 different families in which 7 other children have had the same disease. The clinical picture in these 5 children was identical to that of 16 published cases. The cholestatic syndrome was incomplete. Jaundice was of varying intensity, accompanied by dark colored urine and partially acholic stools. Pruritus was generally severe; hepatomegaly was persistent. Bilirubinemia was increased. Injected bromsulphalein was abnormally retained. The total cholesterol and total lipids of the serum remained normal, even when cholestasis lasted several months. Prolongation of cholestasis led to laparotomy to ascertain the permeability of the extrahepatic bile ducts. The liver was enlarged, greenish, regular, or already nodular. Histological examination of the liver in 4 cases showed portal fibrosis with a moderate number of round, inflammatory cells. In 3 of the cases, the first attack of cholestasis occurred before the age of 6 months, in 2 cases between 6 and 10 months. Each attack was related to an intercurrent infection. Each attack lasted from a few days to 20 months. Hepatomegaly was always observed between the attacks. Of the 5 patients, 2 died. In the 4 families, 6 sibs suffering from the disease died before the age of 5, and the seventh at the age of 8.

1428 OPHTHALMOLOGIC AND GENETIC ASPECTS OF WILSON'S DISEASE. (HEPATOLENTICULAR DEGENERATION).

(E.) Karma, A. (Oulu Univ. Eye Hosp., Finland). *Acta Ophthalmol.* 51(3):383-389, 1973.

A study was made of 2 pairs of siblings with Wilson's disease and 44 family members living in the same locality. Ophthalmologic examination as well as determination of serum copper and ceruloplasmin concentrations were performed on all subjects. In the patients with Wilson's disease a liver biopsy specimen was examined by light microscopy. Of the 4 patients, 1 had no physical sign of the disease. In the 3 symptomatic patients the finding of the Kayser-Fleischer ring led to diagnosis. The asymptomatic patient had no such ring. The Kayser-Fleischer ring appears to develop within the months that neurologic symptoms become manifest. The copper ring disappears gradually during penicillamine treatment. The consanguinity of the 2 families was shown by a genealogical study and suggested an autosomal recessive inheritance of the disease.

1429 RADIONUCLIDE STUDIES ON THE GROWTH OF INTRAHEPATIC TUMORS AND OF THE INFILTRATED LIVER.

(E.) Spencer, R. P.; Witek, J. T. (Yale Univ. Sch. of Med., New Haven, Conn.). *Cancer* 32(4):838-842, 1973.

The suggestion is made that radionuclide scans of the liver can be used to measure the rate of growth of intrahepatic neoplasms. Techniques for accomplishing this are discussed, and the linear growth rate (change in diameter/time) is calculated. In 5 cases of metastatic tumors to the liver, the linear growth rate determined by use of the scans is in the range of 100×10^{-3} to 400×10^{-3} mm/day (periods of observation of from 43 to 694 days). In order to compare single intrahepatic tumors with those which infiltrate the liver, there is a need for estimates of tumor and hepatic weights. In 2 cases of diffuse hepatic involvement (carcinoma of stomach, acute lymphatic leukemia) the estimated change in hepatic weight/day is 1.6 and 30.5 grams. Possible uses of the techniques include showing the time course of hepatic involvement, comparing the growth of hepatic and pulmonary lesions before and after therapy, and comparing the observed rates with various growth hypotheses.

1430 ULTRASTRUCTURE OF CYTOPLASMIC HYALINE INCLUSIONS IN A CASE OF HUMAN HEPATOCARCINOMA.

(E.) Enat, R.; Buschmann, R. J.; Chomet, B. (VA West Side Hosp., Chicago, Ill.). *Gastroenterology* 65(5):802-810, 1973.

In recent publications it has been demonstrated that irregular and globular cytoplasmic hyaline inclusions seen by light microscopy in human hepatocarcinoma are non-membrane bound, fibrillar bodies by electron microscopy similar to Mallory bodies. In the case of human hepatocarcinoma which is presented, morphologically similar globular inclusions seen by light microscopy were entirely different by electron microscopy. Ultrastructurally, three types of inclusions are described. Type I inclusions were small (approximately 1 to 4 μm), single membrane-bound, and compactly filled with a rather homogeneous, finely granular matrix containing a small amount of heterogeneous material. Type II inclusions were on the average slightly larger (approximately 2 to 4 μm), were enclosed by a single or double membrane, and contained various organelles either well preserved or in different stages of degeneration, membranous, granular, and/or diffuse debris, and myelin figures. Type III inclusions were relatively large, single membrane-bound vacuoles containing occasional nondescript debris, glycogen rosettes, and membranous profiles. On morphological grounds, the type II inclusions are interpreted as autophagic vacuoles and the type I and III inclusions as developmental stages of the type II. There were no non-membrane bound, fibrillar inclusions of typical alcoholic hyalin. This study emphasizes that the globular cytoplasmic hyaline inclusions of light microscopy need not only be the previously reported non-membrane bound filamentous bodies but can also be autophagic vacuoles.

1431 LECITHIN CHOLESTEROL ACYL-TRANSFERASE AND LIPOPROTEIN-X IN LIVER DISEASE.

(E.) Ritland, S.; Blomhoff, J. P.; Gjone, E. (Univ. Hosp., Oslo, Norway). *Clin. Chim. Acta* 49(2):251-259, 1973.

Determinations of serum lecithin:cholesterol acyl transferase (LCAT) and the "abnormal serum lipoprotein of cholestasis" (LP-X) have been carried out in 52 patients with different liver disorders and in 20 normal subjects. In acute hepatitis reduced LCAT activity was demonstrated in both LP-X positive and LP-X negative patients. In primary biliary cirrhosis and large bile duct obstruction the presence of LP-X was associated with reduced, normal or increased LCAT activity. No specific LCAT/LP-X pattern in liver diseases were revealed; there was no differentiation between intra- and extrahepatic cholestasis on the basis of these two tests. LP-X was demonstrated in all patients with large bile duct obstruction and primary biliary cirrhosis irrespective the LCAT activity. The LCAT activity observed in obstructive liver disease may depend upon the duration of the disease. In longstanding cholestasis secondary injury of the parenchymatous liver cells supervenes and the LCAT activity may be lowered: The findings of normal serum LCAT activity and occurrence of LP-X may support the theory that increased concentration of free cholesterol and lecithin in cholestasis may exceed the capacity of the LCAT enzyme.

1432 α-FETOPROTEIN AND AUSTRALIA ANTIGEN IN PRIMARY LIVER CANCER.

(E.) Dammacco, F.;

iglietta, A.; Antonaci, S.; Bonomo, L. (Univ. Bari
ed. Sch., Italy). *Digestion* 9(1):41-48, 197.

era from patients with neoplastic and non-neoplastic
iseases, as well as from full-term newborns and
regnant women were examined for the presence of α-
etoprotein (α-FP) by counterimmunoelectrophoresis.
-FP was detected in primary hepatoma (59%) and
onadal teratoblastoma. Positive results were also
btained in a case of colonic carcinoma metastatic
o the liver and in 100% of cord blood sera. Since
ounter-immunoelectrophoresis is approximately inter-
ediate between double diffusion and radioimmunoassay
n terms of degree of sensitivity, it was proposed
hat this technique should be employed routinely for
linical purposes. The frequency of the hepatitis-
ssociated antigen (HBAg) was determined in the sera
f hepatoma patients and of two control groups con-
isting of healthy blood donors and patients with
alignant tumors other than hepatoma. HBAg was
resent in 1 (4.5%) of the 22 hepatoma sera. By
omparison, it was detected in 1 (4%) of the 25 sera
elonging to the neoplastic series and in 5 (1.9%)
f 950 blood donors. It is suggested that primary
epatoma is not directly related to chronic hepatitis
nd/or presence of HBAg. When, however, peculiar
elationships occur between host and the hepatitis
irus, viral hepatitis may progress to liver-cell
arcinoma through the intermediate stage of post-
ecrotic cirrhosis.

33 STUDY OF AUSTRALIA ANTIGEN IN PRIMARY
LIVER CANCERS: ITS RELATION TO ALPHA-
TOPROTEIN. *(Fr.)* Bourgeaux, C.; Trepo, C.;
rdes, M.; Sizaret, P.; Martin, F.; Sananes, R.;
petjian, M.; Klepping, C. (Fac. Med., Dijon,
ance). *Biol. Gastroenterol. (Paris)* 6:133-137,
73.

sts for hepatitis B antigen (HBAg) and α-fetoprotein
re performed on sera from 32 patients (31 of French
igin and 1 Algerian) who were suspected of having
imary liver cancer and 13 patients with diseases
her than primary liver cancer and positive α-feto-
otein tests. The diagnosis of primary liver cancer
s confirmed at autopsy in 17 cases and was based
clinical, endoscopic, and arteriographic findings
the remaining 15 cases. Histological examination
the tumor in autopsied patients showed that 14
re hepatomas, 1 was a cholangioma, and 2 were
patocholangiomas. The test for α-fetoprotein was
sitive in 10 of the 15 autopsied patients with
imary liver cancer. Only 1 of these patients, a
-yr-old Frenchman with no history of blood trans-
sions or viral hepatitis, had a positive test for
Ag. Positive tests for HBAg were also obtained
2 of the controls with positive α-fetoprotein
sts: a 2-yr-old boy with a testicular dysembryoma
had received a blood transfusion and a patient
h viral hepatitis. The percentage of HBAg-
sitive patients with primary liver cancer in this
ries is about the same as in the general population
France, suggesting that HBAg plays little or no
e in the development of primary liver cancer in
nce.

1434 CLINICAL LIVER HETEROTOPIC (AUXILIARY) TRANSPLANTATION. *(E.)* Fortner, J. G.; Kinne, D. W.; Howland, W. S.; Kim, D. K.; Castro, E. B.; Yeh, S. D. J.; Benua, R. S.; Krumins, S. (Mem. Sloan-Kettering Cancer Ctr., New York, N.Y.). *Surgery* 74(5):739-751, 1973.

Heterotopic (auxillary) liver allograft was performed on 3 patients (1 boy and 2 women, aged 4 1/2 to 72 yr) with survival ranging from 35 days to 8 months, 1 remaining alive at 9 months time. Conditions leading to transplant included localized but unresectable adenocarcinoma involving common hepatic and intrahepatic bile ducts, chronic active hepatitis with several episodes of coma, and the absence of extra- and intrahepatic bile ducts. Laboratory tests prior to transplant showed serum total bilirubin ranging from 2.62 to 34 mg %; alkaline phosphatase, 263 to 312 I.U.; and SGOT, 117 to 228 U. One problem encountered in this operation is providing adequate space for the donor liver. In 1 patient the abdominal wall was reconstructed with prosthetic film to close over the auxiliary liver, in the second pneumoperitoneum was used and, in the third, ascites developed, markedly distending the abdomen. The right paravertebral region was chosen for placement of the allograft in all 3 patients for its contour, the ease with which it can be readied to receive the graft, and its proximity to structures necessary for support of the transplant. It is stressed that optimum conditions for the graft appear to be met when there are alterations in splanchnic venous blood flow so that the transplanted liver receives blood preferentially to the recipient's liver. Immune suppression appeared optimal with Cytoxan, low dosages of prednisone, short courses of high-dose methylprednisolone, and high doses of antihuman lymphocyte globulin.

1435 THE VALUE AND LIMITATIONS OF HEPATIC ARTERIOGRAPHY. *(Ger.)* Bucheler, E.; Boldt, I.; Frommhold, H. (Radiol. Clin., Univ. Bonn, Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 119(5):530-544, 1973.

The use of hepatic arteriography resulted in the establishment of correct diagnoses in 296 of 328 patients (90%) with liver diseases confirmed by surgery, autopsy, or the clinical course of the disease. Correct diagnoses were made in 51 of 54 patients (94%) with primary liver cancer, in 71 of 86 (82%) with hepatic metastases, in 37 of 41 (90%) with parasitic diseases, in 20 of 24 (84%) with benign tumors or cysts, in 100 of 105 (95%) with cirrhosis, in 4 of 4 (100%) with vascular disease, and in 13 of 14 (93%) with hepatic trauma. Despite the apparently good results obtained in patients with primary liver cancer, the diagnosis was usually established when tumor growth was advanced because of the relatively late development of symptoms which, in some cases, were atypical. False-positive diagnoses were made on 2 patients (one was diagnosed as having echinococcosis and the other as cirrhotic regeneration nodules), and a false-negative result was obtained in 1 case. Arteriography was less successful in the diagnosis of hepatic metastases since these tumors are generally small and often avascular. False-positive diagnoses of cancer (3 cases) and a cyst (1 case) were obtained in 10% of the patients with parasitic diseases. False-positive diagnoses of echinococcosis (1 case) and cancer (1 case) were made on 2 patients (8%) with benign tumors or cysts, and false-negative diagnoses were obtained in 2. False-positive diagnoses of cancer (3 cases) and chronic hepatitis (2 cases) were made on 5% of the cirrhotics. One false-negative result was obtained on a patient (7%) with hepatic trauma. It is concluded that hepatitic arteriography is a highly specific technique for diagnosing liver diseases and gives results which can be obtained by no other method.

1436 ALTERATION IN LIVER MITOCHONDRIAL METABOLISM IN A PATIENT WITH BILIARY OBSTRUCTION DUE TO LIVER CARCINOMA. *(E.)* Ozawa, K.; Takasan, H.; Kitamura, O.; Yamaoka, Y.; Mizukami, T.; Kamano, T.; Takeda, H.; Honjo, I. (Kyoto Univ. Fac. Med., Japan). *Am. J. Surg.* 126(4):653-657, 1973.

Alteration in liver mitochondrial metabolism was studied in a 65 year old patient with biliary obstruction due to liver carcinoma and in male rabbits. Human biopsy material weighing 0.4 to 0.8 gm was obtained from an area of the liver edge at operation and compared with controls from 21 patients (61 to 69 years old). There was an enhancement of about 200% of normal mitochondria adenosine triphosphate (ATP) synthesis, especially with nicotinamide-adenine dinucleotice linked substrates. The cytochrome $c+c_1$ contents were similar to those of the controls, but the concentrations of cytochromes $a(+a_3)$ and b increased to about 120% of control values. The mitochondrial metabolism of the left lobe increased, probably in a compensatory manner for the damaged right lobe. In the mitochondria from the right lobe, the phosphorylation rates were severely inhibited, especially with glutamate as a substrate. Autopsy specimens were taken 60 minutes after death. The mitochondria in both lobes showed extremely low levels of cytochromes $a(+a_3)$, b, and $c+c_1$. There is a compensatory hyperfunction followed by a depression of mitochondrial metabolism that is parallel to the progressive deterioration of liver viability. Experimental bile duct ligation was performed on healthy young male rabbits in which the left branch of the hepatic bile duct was ligated. In this way, about 60% of the hepatic tissue was damaged by obstructive jaundice. A reduction of about 50% in mitochondrial ATP synthesis was observed in the ligated lobe as early as 48 hours after ligation of the left hepatic bile duct. The phosphorylation rates in the nonligated lobe increased about twofold 2 days after operation and later decreased.

1437 METABOLIC RESPONSES OF THE LIVER OF HUMAN BEINGS AND OTHER MAMMALS TO DEPRIVATION OF PORTAL BLOOD SUPPLY. *(E.)* Ozawa, K.; Kitamura, O.; Yamaoka, Y.; Kamano, T.; Mizukami, T.; Takeda, H.; Takasan, H.; Honjo, I. (Kyoto Univ. Fac. Med., Japan). *Surg. Gynecol. Obstet.* 137(4):623-628, 1973.

The metabolic responses of the liver of 18 human beings (32 to 72 years old), adult male Wistar rats, rabbits, mongrel dogs, and monkeys to deprivation of portal blood supply were studied. The subjects were all subjected to ligation of a branch of the portal vein. In rats, serum glutamic oxalecetic transaminase activity began to rise within 4 hours, reached about 90 times higher than the preoperative level within 12 hours, and rapidly fell to normal at 24 hours. In rabbits, it reached a peak of about 16 times by 24 hours and fell to normal at 48 hours. In 6 patients with a normal value before the operation, the elevated serum glutamic oxalacetic transaminase activity averaged 6 times the preoperative level on the first postoperative day. Portal vein ligation in rabbits resulted in the rapid elevation of serum lactic dehydrogenase, sorbitol dehydrogenase, and malic dehydrogenase to levels as high as in serum glutamic oxalacetic transaminase. Serum leucine aminopeptidase was normal throughout. Electron microscopy showed swelling of mitochondria, decreased density of the matrix, abnormalities in the cristae, and a mild decrease in the number of mitochondria. The glutamic dehydrogenase activity in serum increased in parallel with the decrease of phosphorylation rates of the mitochondria from the ligated lobe. In nonligated lobes, the phosphorylative capacity of mitochondria was enhanced in parallel with the increase of glutamic dehydrogenase activity in serum. The phosphorylation rates in rats rapidly fell to 33% within 3 hours after portal ligation, whereas in rabbits those decreased to 66% within 12 hours. In dogs and monkeys, the phosphorylation rates were slightly decreased. The fatty acid concentration increased markedly within 12 hours, decreased rapidly, and reached the level of the control liver by 48 hours. In the absence of portal blood, the phosphorylative capacity for rats, rabbits, and possibly human beings decrease with progressive evolution of mammals.

1438 PRIMARY MALIGNANT MESENCHYMAL TUMORS (MESENCHYMOMA) OF THE LIVER IN CHILDHOOD. AN ANGIOGRAPHIC-PATHOLOGIC STUDY OF THREE CASES. *(E.)* Stanley, R. J.; Dehner, L. P.; Hesker, A. E. (Mallinckrodt Inst. Radiol., St. Louis, Mo.). *Cancer* 32(4):973-984, 1973.

Primary malignant mesenchymal tumors (mesenchymoma) of the liver in childhood were studied through 3 case histories of a 6 year old boy, and two 10 year old boys. A midstream aortogram and a selective celiac arteriogram were performed which demonstrated: a large hypovascular mass in the upper abdomen projecting slightly to the left (case 1), marked stretching and separation of the intrahepatic branches of the right hepatic artery and displacement to the left of the celiac axis and the common hepatic trunk (case 2), and stretching and separation of the intrahepatic arteries to the right lobe (case 3). Two children had partial hepatectomies and the other had multiple hepatic biopsies to establish the diagnosis. The histopathologic features of the 3 hepatic neoplasms were all very similar. There were 2 basic elements recognized in each of these tumors: anaplastic and ductlike structures. A more or less

mogeneous population of extremely anaplastic and
orly differentiated tumor cells existed in all 3
sions. In some areas, the cells were quite densely
cked with relatively little intercellular space,
ereas in others the background had an edematous
myxoid quality. Irregular clefts were present in
e tissue; however, a convincing demonstration of
endothelial lining was lacking. The other elements
these neoplasms were represented by ductlike
ructures representing either entrapped hepatic
cts or the less favored possibility of neoplastic
ood vessels. These ducts concentrated in the
ea of the tumor closest to the interface between
e uninvolved liver and the mass. Between the main
dy of tumor and the attached uninvolved liver, a
brous interface had formed. It was composed of
mnants of compressed hepatic parenchyma and small
cts.

39 HEMANGIOSARCOMA OF THE LIVER COMPLICATED BY DISSEMINATED INTRAVASCULAR COAGULATION.
CASE REPORT. *(E.)* Truell, J. E.; Peck, S. D.;
iquam, C. W. (Presbyterian Med. Ctr., Denver, Colo.).
stroenterology 65(6):936-942, 1973.

case report is presented of a 68 year old male with
mangiosarcoma of the liver complicated by dissemi-
ted intravascular coagulation. Symptoms leading to
s first hospital admission included a 2 month his-
ry of increasing weakness and fatigue, an 8-lb
ight loss, anorexia, nausea, epigastric fullness,
d discomfort. A liver scan showed hepatomegaly
th irregular uptake in both lobes and interpreted
diffuse hepatocellular disease consistent with
rrhosis. About 6 weeks later, he was readmitted
th 2 weeks of increasing ankle swelling, nausea,
d vomiting. Two months after his original admis-
on, he died. An autopsy was performed and the
gnificant findings are presented. The peritoneal
vity contained 500 cc of hemorrhagic fluid with a
matocrit of 45%. The liver weighed 3900 g. Its
psular surface was smooth, with many soft, fluc-
ant, blue-black cystic spaces. The parenchyma
s honeycombed by cystic vascular spaces, measuring
to 6 cm in diameter, several containing deposits
fibrin. Histological examination revealed a
ffuse variegated process with vascular spaces
ned by proliferating endothelial cells. The
mor nodules were highly cellular, forming occa-
onal vascular channels, containing red blood
lls. The cytology was that of a sarcoma with
rkedly pleomorphic, hyperchromatic nuclei and oc-
sional mitotic figures. The spleen weighed 120 g
d was unremarkable. The lungs contained changes
chronic obstructive disease with centrilobular
physema and foci of pleural and interstitial fi-
osis. The bone marrow was mildly hypercellular
th adequate numbers of megakaryocytes present.

40 SEGMENTAL OBSTRUCTION OF THE BILE DUCT.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

1458 EFFECT OF PHENOBARBITONE ON BILE FLOW AND BILIRUBIN METABOLISM IN MAN AND THE RAT. *(E.)* Maxwell, J. D.; Hunter, J.; Stewart, D. A.; Carrella, M.; Williams, R. (King's Coll. Hosp., London, England). *Digestion* 9(2): 138-148, 1973.

A group of male Wistar rats received phenobarbitone (90 mg/kg/day, i.p. for up to 10 days). Bile flow peaked after 4-6 days at about 50% above control levels of 250 μl/100 g/hr. Liver weight rose progressively with a striking early increase in cytochrome P450 to 2.5 times the control level of 0.70 μmol/mg protein. However, it is noted that the ratio of the increase in liver weight to body weight did not parallel the increase in bile flow. Bilirubin glucuronyl transferase activity increased 9%. Plasma bilirubin levels and excretion of endogenous bilirubin remained unchanged, indicating that phenobarbitone had no effect on bilirubin metabolism. Phenobarbitone was similarly administered to 4 homozygous Gunn rats and some increase in the excretion of a large exogenous load of conjugated bilirubin was noted. Phenobarbitone (60-100 mg/day for one month) was given to 12 patients (9 males and 3 females, all adults) with unconjugated hyperbilirubinemia of Gilbert's syndrome. A mean reduction of 60% in plasma bilirubin from 1.92 to 0.74 mg/100 ml was observed after 4 weeks of treatment. Accompanying this was a large increase in urinary D-glucaric acid excretion from 9.9 to 37.2 μmol/day, indicating that even with the low dose used, there was increased activity of hepatic microsomal enzymes. BSP Tm and BSP S did not significantly change. Thus, at these doses, the drug caused no change in bile flow. There was a significant correlation between plasma bilirubin levels and glucaric acid excretion in patients with Gilbert's syndrome, suggesting that the reduction in plasma bilirubin is related to increased activity of hepatic microsomal enzymes. A similar correlation was noted in 56 control subjects without liver disease who also underwent phenobarbitone treatment.

1459 ENTEROHEPATIC CIRCULATION OF BILIRUBIN IN PRENATAL AND POSTNATAL LIFE: AN ALTERNATIVE PATHWAY FOR CONTROL OF NEONATAL HYPERBILIRUBINEMIA. *(E.)* Lampe, L.; Hafez, E. S. E. (Dept. Gynecol.-Obstet., Wayne State Univ., Detroit, Mich.). *J. Reprod. Med.* 11(5):225-232, 1973.

The interruption of the enterohepatic circulation of bilirubin is proposed as a control of neonatal hyperbilirubinemia. Physiologic neonatal jaundice occurs only in primates. The metabolism of adult and fetal bilirubin varies with respect to hemoglobin synthesis, life span of erythrocytes, liver enzyme kinetics, and excretory processes. After hemoglobin-bilirubin transformation, the pigment is bound to albumin and transported to the liver. Mammalian liver contains uridine diphosphoglucuronic acid transferase (UDP transferase) which transfers the glucuronic acid from uridine diphosphoglucuronic acid (UDPGA) to the bilirubin. This produces a water soluble form more readily excreted. Since all excreted bilirubin in mammals is conjugated, there is no evi-

ence of an enterohepatic circulation of bilirubin
n normal adults. Fetal hemopoiesis is characterized
embryonic, fetal, and adult types of hemoglobin
ynthesis, shorter life span of erythrocytes, and
igher hemoglobin concentration. The UPDGA and UDP-
ransferase content of fetal liver is lower but
ises soon after birth. The presence of β-glucuro-
idase in the fetal and neonatal intestine makes
ssible hydrolysis of conjugated bilirubin. This
nconjugated bilirubin is rapidly absorbed from the
mall intestine, but the transplacental gradient
llows excretion from fetus to mother. When the
ord is cut, the newborn is deprived of placental
learance. The interruption of this enterohepatic
irculation of bilirubin with medicinal charcoal,
ynthetic resin, or agar is proposed as an effective
ethod of reducing high unconjugated hyperbilirubine-
ia in lieu of photochemical methods now in vogue.

460 ETHANOL IN THE PREVENTION OF NEONATAL HYPERBILIRUBINAEMIA. *(E.)* Jouppila, P.;
oivisto, M.; Suonio, S. (Dept. Obstet. Gynecol.,
niv. Oulu, Finland). *Acta Paediatr. Scand.* 62(5):
01-504, 1973.

The effect of ethanol on the bilirubin values of newborns was studied. Seventy-four pregnant women with mild pre-eclampsia and suspected postmaturity were given 80 g of ethanol orally or 63, 94 or 102 g i.v. Nineteen mothers and their offspring served as controls. The bilirubin levels of the newborn were not significantly lower during the first 6 days of life compared with the controls. The highest bilirubin level was reached on the third to fifth day in all the groups. The results differ from those reported earlier.

1461 IRON METABOLISM AND STORAGE IN GILBERT'S DISEASE, AND IN ROTOR'S AND DUBIN-JOHNSON'S SYNDROMES. *(E.)* Burger, T.; Gogl, A.; Javor, T.; Patakfalvi, A. (Univ. Med. Sch., Pecs, Hungary). *Acta Med. Acad. Sci. Hung.* 29(3-4):331-338, 1972.

462 HISTIOCYTIC MEDULLARY RETICULOSIS APPEARING AS ACUTE HEPATIC NECROSIS.
.) Steiner, J. A.; Perkins, K. W.; McGovern,
. J. (Dept. Med., Univ. Sydney, Australia).
ed. J. Aust. 2(10):496-498, 1973.

he case history of a 26-year-old process worker
ith histiocytic medullary reticulosis is pre-
ented. He was well until 4 weeks before ad-
ission, when anorexia and nausea commenced,
ollowed after several days by vomiting and in-
reasingly severe right hypochondrial pain.
aundice was first observed 3 weeks prior to his
dmission and increased steadily. On the day
efore admission he developed severe pleuritic
ain in the left hypchondrium. The liver was en-
arged 8 cm and the spleen 6 cm below the costal
argin and both were extremely tender. During
he first 5 days in the hospital, the upper
bdominal pain and vomiting persisted and the
atient's signs remained unchanged. On the fifth
ay, therapy with prednisone 60 mg/day was commenced
nd the patient's condition improved subjectively.
n the tenth hospital day, liver biopsy showed
entrilobular necrosis with no inflammatory re-
ponse except in the portal tracts. There were
lso groups of cells suggestive of extramedullary
rythropoiesis. The dose of prednisone was re-
uced to 10 mg/day by day 16; clinical deteriora-
ion occurred. The dose of prednisone was in-
reased, but clinical deterioration continued.

The significant findings at autopsy were as follows. The liver was enlarged; the cut surface showed prominence of markings with visible red centers in the lobules. The lungs were heavy. There were petechial spots in the pleura and hemorrhagic edema in the lung tissue itself. On microscopic section, the normal splenic architecture was replaced by proliferations of histiocytes of varying grades of malignancy. In the liver, there was widespread centrilobular necrosis, malignant transformation of the Kupffer cells, and erythrophagocytosis and foci of erythropoiesis.

Acute Viral Hepatitis

1467 REASONS FOR AND AGAINST CORTICOSTEROID THERAPY IN VIRAL HEPATITIS. *(Fr.)* Biron, A. (d'Orsay Hosp., Paris, France). *Rev. Fr. Gastroenterol.* (89):53-56, 1973.

Complications developed in 23.9% of 196 patients with liver disease who received corticosteroids. Corticosteroids were used to treat 84 patients with acute hepatitis, 70 with chronic hepatitis, and 42 with cirrhosis. Corticosteroids were only given to patients with acute hepatitis if they were over 60 yr old and had elevated serum transaminase activities or if they had bilirubin levels greater than 120 mg/liter and disturbances in the prothrombin complex which showed no improvement over a 2-week period. In chronic hepatitis and cirrhosis, corticosteroids were limited to patients with signs of progressive disease (elevated serum transaminase levels or large decreases in total cholesterol) which did not respond to choleretic, hepatoprotective, or lipotropic agents. Of the 42 cirrhotics, 9 developed rebound, 14 diabetes, 3 peptic ulcers, and 3 fractures resulting from osteoporosis. Because of the high incidence of complications among patinets treated with corticosteroids, these agents have recently been replaced by immunosuppressants (50-150 mg/day azathioprine, 50-100 mg/day 6-mercaptopurine, and 6-8 mg/day chlorambucil) in the treatment of chronic hepatitis. It is recommended that corticosteroids be associated with immunosuppressants for the best results.

1468 AUSTRALIA ANTIGEN IN MOSQUITOES. FEEDING EXPERIMENTS AND FIELD STUDIES. *(E.)* Blumberg, B. S.; Sills, W.; Millman, I.; London, W. T. (Inst. Cancer Res., Philadelphia, Pa.). *Res. Commun. Chem. Pathol. Pharmacol.* 6(2):719-732, 1973.

Individual mosquitoes trapped in the field in Africa and mosquitoes studied in a laboratory were tested for Australia antigen (Au) by radioimmunoassay. *Anopheles stephensi* fed on blood containing Au had detectable Au up to 48 hours after feeding. Ten of 42 mosquitoes trapped in residential areas in East and Central Africa had detectable Au. In addition, one collection of eggs from *Anopheles stephensi* which had fed on blood containing Au was found to have Au. These findings support the hypothesis that mosquitoes could be a vector of Australia antigen and hence hepatitis virus for man. They suggest an additional hypothesis that Au could be maintained in mosquito populations by way of maternal transmission.

1469 GLUCOSE TOLERANCE AND METABOLIC CHANGES IN HUMAN VIRAL HEPATITIS. *(E.)* Record, C. O.; Alberti, K. G. M. M.; Williamson, D. H.; Wright, R. (King's Coll. Hosp. Med. Sch., London, England). *Clin. Sci. Mol. Med.* 45(5):677-690, 1973.

Glucose tolerance and metabolic changes after intravenous glucose were studied in 15 patients with acute viral hepatitis and in 8 patients after recovery. In the acute stage glucose tolerance was significantly impaired compared with control subjects or with patients after recovery from hepatitis. Serum insulin concentrations were significantly higher in fasting acute hepatitis patients than in control subjects and the time-integrated serum insulin concentration in the first 5 min after glucose was inappropriately high for the observed glucose disappearance rate, indicating insulin resistance. Serum growth hormone concentrations in male acute hepatitis patients were significantly higher than controls and suppressed poorly. Fasting blood lactate concentrations were significantly elevated and after intravenous glucose there was a variable response. 2-Oxoglutarate, glutamate and glutamine concentrations from blood of fasting subjects, were significantly higher in acute hepatitis patients than controls. There were no significant differences in blood ketones, glycerol and plasma free fatty acid concentrations from fasting subjects, but plasma triglycerides were significantly increased in the acute hepatitis patients. The results indicate that viral hepatitis is associated with glucose intolerance and insulin resistance. After recovery the lactate response after glucose is diminished compared with controls.

1470 HEPATITIS B ANTIGEN IN FAMILIES OF BLOOD DONORS. *(E.)* Berris, B.; Wrobel, D. M.; Sinclair, J. C.; Feinman, S. V. (New Mt. Sinai Hosp., Toronto, Canada). *Ann. Intern. Med.* 79(5):690-693, 1973.

The family members of 46 volunteer Red Cross blood donors positive for HB Ag were tested for HB Ag. The prevalence of positive relatives was 13%, compared with 0.15% in the donors. Seventeen of the 18 positive relatives were from families who originated in countries where the HB Ag carrier rate is high

d only one was from countries where it is low.
e high prevalence countries include: Italy, China,
eece, West Indies, Malta, Pakistan, and Nigeria.
e low prevalence countries are: Canada, Great
itain, Germany, and South Africa. The prevalence
positive kindred from high-prevalence countries
s 23%, and it seemed to be more related to ethnic
igin than country of birth. Among the first-
gree relatives the positive members were approxi-
tely equally distributed among siblings, parents,
d offspring. None of 28 marital partners was
sitive. Whether the family clustering is owing
an epidemiologic or genetic relationship requires
rther study.

71 ACUTE VIRAL HEPATITIS: COURSE AND INCIDENCE OF PROGRESSION TO CHRONIC HEPATITIS.
.) Vittal, S. B. V.; Thomas, Jr., W.; Clowdus,
F. (Chicago Med. Sch., Ill.). *Am. J. Med.*
(6):757-761, 1973.

a prospective study, 53 consecutive patients with
opsy-proved acute viral hepatitis were observed
rially and treated identically during a 15 week
riod following the onset of jaundice. They were
vided into four groups on the basis of the pres-
ce or absence of hepatitis-associated antigen
AA) and the presence or absence of parenteral ex-
sure to a potential source of HAA. Even though
e degree of hepatocellular necrosis was greater
the HAA-positive group, irrespective of the portal
entry of HAA, 89.2% of HAA-positive and 83.3% of
A-negative subjects made equally rapid and complete
covery within 6 weeks after the onset of illness.
e development of chronic active hepatitis in the
mainder was associated with either the persistence
HAA in the serum beyond the thirteenth week of
lness or the presence of a positive lupus erythema-
sus test during the first and subsequent weeks of
lness. It is concluded that in the majority of
tients with acute viral hepatitis, recovery is
mplete but that chronic active hepatitis will
velop in patients in whom HAA persists beyond 13
eks of illness or in whom the lupus erythematosus
st is positive and antinuclear antibody (ANA) is
esent at the onset of illness (11.3%).

72 IMMUNOAGGLUTINATION ELECTRON MICROSCOPIC STUDY ON VIRUS-LIKE PARTICLES AND AUSTRALIA
TIGEN IN LIVER TISSUE. *(E.)* Huang, S.-N.; Groh,
(Dept. Pathol., McGill Univ., Montreal, Canada).
. *Invest.* 29(4):353-366, 1973.

mogenized liver tissues from five patients suffer-
g from persistent Australia antigenemia and chronic
tive hepatitis (type B) were shown by electron
croscopy on phosphotungstic acid-stained prepara-
ons to contain noncoated virus-like particles 270
d 290 Å in size and Australia antigen (Au-Ag)
nsisting of Dane particles 420 to 460 Å in size,
laments 200 to 260 Å in diameter, and a few small
herical particles 200 to 220 Å in diameter. A sim-
e method of immunoagglutination electron microscopy
s used to facilitate the detection of Australia
tigen. The method includes maceration of liver
tissue, digestion with Pronase to clear up the cell debris, and reaction of the digested homogenate with rabbit Au-Ag antiserum. The tissue fluids were stained with phosphotungstic acid for electron microscopic examination. The noncoated particles were found singly or in clusters irrespective of the treatment with Au-Ag antiserum. These particles showed icosahedral symmetry and presence of capsomere-like surface structures. They are morphologically identical with the internal core of the Dane particles. The immunoagglutination electron microscopy showed formation of Au-Ag immune complexes, which are composed exclusively of Dane particles, filaments, and small spherical particles, but not the previously described noncoated particles. Similar study made on the serum showed identical Au-Ag complexes and no noncoated particles. The results indicate that the noncoated particles are antigenically different from the Au-Ag, which is probably the virus-induced protein coat that forms the envelope of the Dane particles, the filaments, and the small particles. The finding of the noncoated and the coated particles (the Dane particle) is probably pathognomonic for type B viral hepatitis. Pronase digestion did not affect the immunoreactivity of Au-Ag nor the agglutinin effect of the antiserum in this study. The method is useful in the study of antigenic characterization of hepatitis virus and its related products.

1473 VIRAL HEPATITIS B IN NEONATES AND INFANTS.
(E.) Schweitzer, I. L.; Dunn, A. E. G.; Peters, R. L.; Spears, R. L. (John Wesley County Hosp., Los Angeles, Calif.). *Am. J. Med.* 55(6): 762-771, 1973.

The clinical and biochemical course in 17 hepatitis B antigen (HBAg)-positive infants is described. Their mothers had acute hepatitis B while pregnant or in the first 2 postpartum months. Neonatal infection developed in 1 of 10 babies when maternal hepatitis occurred in the first 2 trimesters and in 16 of 21 when it occurred in the third trimester or within 2 months after delivery. The cord bloods of 7 infants who become antigen-positive were tested and HBAg was detected in 4. In 2 of the 17 infected infants acute icteric hepatitis developed at 3 and 4 months of age. In these cases, the illness was mild, HB antigenemia was transient, and significant titers of hepatitis B antibody (HBAb) developed following recovery. Thirteen infants who became infected showed no clinical signs of illness, but their serums remained consistently antigen-positive for up to 39 months with prolonged serum glutamic pyruvic transaminase (SGPT) elevations. Liver biopsies performed on 10 infants between 3 and 27 months of age revealed the histologic features of unresolved hepatitis; increased portal fibrosis was observed in 1 case. Electron microscopic examination revealed 24 nanometer virus-like particles in hepatocyte nuclei of 6 of 9 cases studied. The most consistent pathologic change seen at the ultrastructural level was cytoplasmic "ballooning" which occurred in some areas of every case. The most common response of neonates to hepatitis type B virus (HBV) exposure is chronic, hepatitis B with the histologic features of unresolved hepatitis. Long-term follow-up will be required to determine the final evolution of this lesion. An occasional neonate in whom acute icteric hepatitis B develops may experience rapid healing with prompt loss of antigenemia followed by the development of significant HBAb titers.

1474 STUDIES ON THE INCIDENCE OF HEPATITIS IN CLINICALLY NORMAL, AUSTRALIA ANTIGEN POSITIVE BLOOD DONORS.

(Ger.) Eisenburg, J.; Meister, P.; Fruhauf, S.; Greis, I.; Krumpoch, B.; Weinzierl, M.; Grunst, J.; Munte, A.; Rasch, L. (1st Med. Clin., Univ. Munich, Germany). *Klin. Wochenschr.* 51(23):1143-1150, 1973.

Routine testing of 7000 apparently normal blood donors showed that 95 were positive for Australia antigen (HBAg). Liver biopsies, performed by Menghini's technique on 62 of these 94 donors, revealed that 9 (1[illegible]%) had chronic persistent hepatitis, 10 (16%) had active hepatitis, 30 (49%) had changes consistent with unresolved mild hepatitis or minimal liver damage, while only 13 (21%) of these HBAg-positive donors had no evidence of liver disease. Follow-ups of 7 of the 10 patients with active hepatitis showed that one had a protracted form and another developed chronic active hepatitis. None of the patients with chronic persistent hepatitis developed active forms of the disease. In donors with active or chronic persistent hepatitis, good correlations were found between histological and biochemical findings (serum bilirubin, SGOT, SGPT, cholinesterase, alkaline phosphatase, plasma proteins, immunoglobulins, and prothrombin time), while biochemical findings were completely normal in patients with minimal liver damage. Tests for HBAg remained positive for more than 12 months in 26 of the 62 biopsied patients; these included 6 patients with chronic persistent hepatitis. Of the HBAg-positive donors, 13 were patients who repeatedly donated 500 ml/week of plasma; 6 developed chronic persistent hepatitis. Because of the small number of patients in this group, it could not be determined whether an immune deficiency is involved in the development of this form of hepatitis in plasma donors.

1475 CHOLESTATIC FORMS OF VIRAL HEPATITIS.

(Fr.) Laverdant, C.; Cristau, P.; Molinie, C.; Essioux, H.; Duret, J. C. (H. I. A. Begin, St. Mande, France). *Ann. Med. Interne (Paris)* 124(8/9):607-610, 1973.

Although the cholestatic form of viral hepatitis usually accounts for no more than 1% of all cases, 27 of 402 patients treated between August 1971 through July 1972 had this form. These 27 patients consisted of 22 men and 5 women, aged 18-50 yr. Histories of contact with hepatitis patients were obtained in 19 cases (14 in France and 5 abroad). Australia antigen was present in 12 (44%) patients with the cholestatic form of viral hepatitis in contrast to 11.54% in all patients with viral hepatitis. Four of the 5 patients who had been repatriated from Africa were positive for Australia antigen. In contrast to ordinary viral hepatitis, which reaches a peak between November and January, the cholestatic form reached its peak in February and March, indicating that type B virus was involved. The most common clinical symptoms of cholestatic viral hepatitis were pruritis (17 cases) and hepatomegaly (19 cases). Serum bilirubin levels, which were higher than 100 mg/liter on day 5 in all cases, reached a maximum (155 ± 22 mg/liter) on day 20 and remained elevated as long as 4-5 months. Alkaline phosphatase values peaked on day 10 and decreased progressively until the 6th month when they increased again. In many patients SGPT activities decreased more rapidly than in the common form of viral hepatitis but increased again between the 3rd and 5th month. Hyperlipidemia and hypertriglyceridemia were observed. Electrophoresis showed a great increase in β-lipoproteins and the absence of α- and pre-β-lipoproteins. Results of the thymol turbidity test normalized more rapidly than in the common form of viral hepatitis. Although 19 of these 27 patients were less than 30 yr old, recovery was slow and hepatitis persisted for 4-7 months in 6 cases. Two patients died: one of hepatic coma on day 21 and the other of gastrointestinal bleeding during the 2nd month.

1476 EXPERIENCE IN THE TREATMENT OF HEPATIC FAILURE BY INTERMITTENT LIVER HEMOPERFUSIONS.

(E.) Abouna, G. M.; Fisher, L. McA.; Porter, K. A.; Andres, G. (Med. Coll. Georgia, Augusta). *Surg. Gynecol. Obstet.* 137(5):741-752, 1973.

Thirty-three clinical *ex vivo* liver hemoperfusions were used for the treatment of deep hepatic coma in ten patients. The *ex vivo* livers came from 22 pigs, 7 baboons, 2 human cadavers, 1 calf, and 1 Macaca monkey. Perfusions were maintained for 5 to 52 hours using a standardized perfusion technique. Normal consciousness was restored in 5 of the patients, and 2 of these have survived for more than 2 years after treatment. Consciousness could be restored in all of the patients when the baboon liver was used, the success rate was only 30% when pig liver was used. Serious complications were rare, and bleeding problems were not encountered. Immunologic problems occurred only with pig liver perfusions, and these included clinical anaphylactic reaction, development of species-specific antibody, cross reacting antibody, and antiporcine serum protein antibody. Histologic and immunofluorescent observations showed acute humoral heterograft rejection in porcine but not in the baboon livers. Intermittent liver perfusions were capable of restoring consciousness on repeated occasions in the same patient however, ultimate survival was dependent upon the degree of initial damage of patient's own liver and on the development of extrahepatic complications. Intermittent *ex vivo* perfusions using the baboon liver have a definite place in the treatment of hepatic coma in patients with acute liver necrosis and in selected patients with chronic irreversible liver disease who might be supported for short periods while awaiting liver transplantation.

1477 CELL-MEDIATED IMMUNITY TO HEPATITIS-ASSOCIATED ANTIGEN (HAA) DEMONSTRATED BY LEUCOCYTE MIGRATION TEST DURING AND AFTER ACUTE B

HEPATITIS. *(E.)* Frei, P. C.; Erard, P.; Zinkernagel, R. (Hospital Cantonal Univ., Lausanne, Switzerland). *Biomedicine* 19(9):379-383, 1973.

Circulating leukocytes from patients with hepatitis were assayed for migration inhibition in the presence of purified hepatitis-associated antigen (HAA) using an agarose technique. The following groups of patients were used: 9 healthy individuals, 8 patients with hepatitis, and 9 patients who had recovered from hepatitis. A significant inhibition of leukocyte migration by purified HAA was observed in a group of 9 individuals who had recovered 5 to 30 months previously from HAA-positive hepatitis and who no longer had detectable serum HAA. In contrast, a stimulation of leukocyte migration was observed in 8 patients during the course of acute hepatitis, while the HAA was detectable in the serum; furthermore leukocytes from 9 normal individuals, who had no previous history of hepatitis, were not inhibited by HAA. A significant migration inhibition could be demonstrated with purified antigen, but not with partially or non-purified HAA. PPD was also used as an antigen for migration inhibition of leukocytes from these same individuals and the results obtained were found to correlate regularly with PPD-delayed skin-tests. The results suggest the development of specific cell-mediated immunity to HAA after the recovery from acute B-virus hepatitis.

LIVER AND BILIARY TRACT

Chronic Hepatitis

1489 COMPLEMENT AND LIVER CELL FUNCTION IN 53 PATIENTS WITH LIVER DISEASE. *(E.)* Kourilsky, O.; Leroy, C.; Peltier, A. P. (Tenon Hosp., Paris, France). *Am. J. Med.* 55(6):783-790, 1973.

Serum complement levels were studied in 53 patients with various liver diseases. The total serum complement level (CH50) was raised in 28, normal in 12 and low in 13 patients. Levels of C4, C2 and C3 in general parallelled total complement levels. Significant positive correlations were obtained between the total complement and albumin, cholesterol, fibrinogen, proaccelerin, and prothrombin. Significant correlations were noted between the levels of C4 and C3 and those of certain coagulation factors, and between the levels of C2 and fibrinogen. C4 was positively correlated with cholesterol, prothrombin time, and prothrombin; C2 was positively correlated with fibrinogen, proconvertin-Stuart factor, and prothrombin; and C3 was positively correlated with albumin, cholesterol, fibrinogen, prothrombin time, preconvertin-Stuart factor, proaccelerin, and prothrombin. The data obtained suggest that, in the majority of cases, lowering of serum complement levels is related to defective hepatic synthesis, providing further support for the role of the liver in the synthesis of some complement components.

1490 MULTISYSTEM INVOLVEMENT IN CHRONIC LIVER DISEASE. STUDIES ON THE INCIDENCE AND PATHOGENESIS.

(E.) Golding, P. L.; Smith, M.; Williams, R. (King's Coll. Hosp. Med. Sch., London, England). *Am. J. Med.* 55(6):772-782, 1973.

The incidence and pathogenesis of multisystem involvement in chronic liver disease were studied in a total of 218 patients. Sjogren's syndrome occurred in 37%, renal tubular acidosis in 32%, pulmonary diffusion defects in 26% and peripheral neuropathy in 10% of patients with active chronic hepatitis, primary biliary cirrhosis or cryptogenic cirrhosis. The incidence of certain other conditions determined from clinical features alone was lower; these included arthropathy in 14%, thyroid disorders in 10%, skin lesions in 17% and colitis in 5%. In the complete series of 218 patients, 125 (57%) had involvement of at least one organ other than the liver, such involvement being significantly more common in those with active chronic hepatitis (63% of cases) and primary biliary cirrhosis (68%) than in those with cryptogenic cirrhosis (38%). In a number of patients, prednisone therapy was followed by both subjective and objective improvement in the features of the multisystem involvement. No correlation could be found between multisystem involvement and the presence of mitochondrial, smooth muscle or antinuclear antibodies in the serum or with the serum levels of immunoglobulins A (IgA), M (IgM) and G (IgG). Histologic examination of the various organs disclosed dense infiltration with small lymphocytes, suggesting that delayed hypersensitivity reactions were involved in the production of tissue damage. In support of this was the demonstration of cell-mediated reactivity *in vitro* to salivary or renal antigens in 42% of the patients with Sjogren's syndrome and in 62% of those with renal tubular acidosis, respectively. These findings, together with the frequency and similar pattern of multisystem involvement in the three conditions, suggest a common pathogenetic mechanism, and disordered cellular immune reactions directed primarily against the liver could affect other organs as a result of cross antigenicity.

1491 HISTOLOGICAL CHANGES IN TWO SEROLOGICALLY DEFINED GROUPS OF CHRONIC HEPATITIS.

(E.) Christoffersen, P.; Dietrichson, O.; Nielsen, J. O.; Elling, P. (Commun. Hosp., Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand* [*A*] 81(5):698-702, 1973.

The histological features of 42 consecutive patients with biopsy verified chronic hepatitis and available serum specimens were studied. The patients were divided into two groups: group 1: 12 patients with persistent Au-antigenemia but neither antinuclear antibodies (ANA) nor smooth muscle antibodies (SMA) and group 2: 27 patients without detectable Au-antigen but with ANA and/or SMA. There is a significantly higher incidence of parenchymal inflammation and a significantly higher degree of portal inflammation in group 2 than in groupl, just as there is more pronounced occurrence of plasma cells. A morphological follow-up of 92 percent of the patients shows a significantly more frequent development of cirrhosis in the group with ANA and/or SMA. Significantly elevated values of IgA and IgG occurred in the group with autoantibodies. Abnormal bile duct epithelium is demonstrated only in the group without autoantibodies.

1492 HIGH TITRES OF ANTIBODIES AGAINST RUBELLA AND MORBILLI VIRUS IN PATIENTS WITH CHRONIC HEPATITIS.

(E.) Closs, O.; Haukenes, G.; Blomhoff, J. P.; Gjone, E. (Inst. Exp. Med. Res., Oslo, Norway). *Scand. J. Gastroenterol.* 8(6):523-528, 1973.

The presence of rubella and morbilli haemagglutination-inhibiting antibodies was studied in 40 patients with chronic liver disease. In patients with chronic hepatitis highly elevated titres were found in 12 out of 19 patients, the geometric mean titre of antibodies against both viral antigens being about 8 times that of the control group. Normal titres were found in sera from patients with primary biliary cirrhosis, and titres were only slightly increased in patients with other types of cirrhosis. Linear correlation between viral antibody titres and IgG concentration could not be demonstrated. Possible causes of the observed high titres of rubella and morbilli antibodies include: abnormal amounts of antigen and an abnormal immune response.

1493 SERUM "VIRUS-LIKE" PARTICLES IN CHRONIC HEPATITIS AND CIRRHOSIS: RELATION TO IMMUNOLOGICAL TESTS FOR HEPATITIS B ANTIGEN.

(E.) Jokelainen, P. T.; Krohn, K.; Finlayson, N. D. C.; Prince, A. M. (1st Dept. Pathol., Univ. Helsinki, Finland). *Gastroenterology* 65(5):796-801, 1973.

The sera of 69 patients with chronic hepatitis and cirrhosis were investigated separately for the hepatitis B antigen immunologically and for the electron-microscopic particles associated with that antigen. The antigen was found in 20 cases, and electron microscopic particles were present in 19 of these. Electron-microscopic particles morhpologically indistinguishable from these were found in 5 additional cases where hepatitis B antigen could not be demonstrated. It is possible that the hepatitis B antigen was present, but in amounts too small to detect immunologically, or that these particles did not contain the antigen. Large 430-Å diameter spheres were found in 12 cases, and were significantly associated with the small 200-Å diameter spheres and rods, the large spheres being found alone in only 1 case.

1494 INFUSION OF HEPATITIS-B ANTIBODY IN ANTIGEN-POSITIVE ACTIVE CHRONIC HEPATITIS.
(E.) Reed, W. D.; Cullens, H.; Eddleston, A. L. W. F.; Williams, R.; Zuckerman, A. J.; Peters, D. K.; Williams, D. G.; Maycock, W. D. A. (Lister Inst. Prev. Med., Elstree, England). *Lancet* 7842:1347-1351, 1973.

The effects of infusion of an immunoglobulin preparation with a high titre of antibody to hepatitis-B antigen (HBAg) were investigated in six patients with active chronic hepatitis, in five of whom HBAg was persistently detected in the serum. The intravenous infusions were well tolerated and only two patients showed minor and transient evidence suggesting an immune-complex reaction. One patient developed transient microscopic hematuria 24 hours after treatment; another case showed an increase in proteinuria from 160 to 770 mg/24 hr on the second day. Complexes containing HBAg were demonstrable after the infusion by electron microscopy in four cases, but in three of these complexes were also present beforehand. Complement levels and C3 conversion products were consistent with the presence of immune complexes. Clearance of antigen from the circulation for up to 9 days was achieved in the two cases with low initial titres of HBAg.

1495 THE RELEVANCE OF A SEROLOGICAL CLASSIFICATION OF CHRONIC HEPATITIS. *(E.)*
Dietrichson, O.; Nielsen, J. O.; Elling, P.; Christoffersen, P. (Commun. Hosp., Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand* [*B*] 81(5):519-524, 1973.

Forty-two consecutive patients with biopsy verified chronic hepatitis and available serum specimens were examined for the occurrence of Australia antigen, antinuclear antibodies, smooth muscle antibodies and mitochondrial antibodies. Twleve patients with persistent Australia antigen, but without circulating autoantibodies (group 1) were compared with twenty-seven patients without Australia antigen, but with circulating autoantibodies (group 2). Young males with a history of serum hepatitis were predominant in group 1, while most of the patients in group 2 were middle-aged women with an insidious onset of the disease. The biochemical activity of the liver disease was more pronounced in group 2. There are significantly more patients with hypoalbuminemia in group 2 than in group 1. The values of IgA and IgG were significantly higher in group 2 than in group 1. It is concluded, that the histological defined chronic hepatitis may include several disease entities of which at least two can be separated by the serology. The relevance of this classification is supported by the fact, that there are more patients developing cirrhosis in group 2 than in group 1.

1496 AUSTRALIAN ANTIGEN IN PATIENTS WITH CHRONIC HEPATITIS AND CIRRHOSIS OF THE LIVER.
(Rus.) Loginov, A. S.; Yartseva, A. M.; Perova, S. D. (All-Union Sci. Res. Inst. Gastroenterol., Moscow, USSR). *Vestn. Akad. Med. Nauk SSSR* (3):50-54, 1973.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

1497 ETHANOL METABOLISM IN 18 SUBJECTS WHO DRINK LARGE QUANTITIES OF ALCOHOL AND HAVE NORMAL LIVER FUNCTION. *(Fr.)* Thomas, M.; El Guedri, H.; Berthaux, N.; Schwarzman, V.; Infante, R. (St. Antoine Hosp., Paris, France). *Biol. Gastroenterol. (Paris)* 6:139-149, 1973.

After 5-45 days (mean 18.8 days) of abstention and ingestion of 0.8 g/kg ethanol diluted in 3 times its volume of water and drunk over a period of 30 min, alcohol metabolism was studied in 18 subjects (17 men and 1 woman, aged 32-73 yr) who had drunk 160-180 g/day (mean 296 g/day) of ethanol for 13-53 yr (mean 30 yr), had no clinical signs of cirrhosis or neurological manifestations of chronic alcoholism, normal or slightly abnormal liver function tests, and essentially normal liver histology (11 had some evidence of fatty liver and 1 of siderosis). Controls consisted of 7 subjects (6 men and 1 woman, aged 33-62 yr) who were nonalcoholics and had no gastrointestinal or liver disease. Although blood alcohol curves followed a similar course in alcoholics and controls, all of the alcoholics had higher blood alcohol peaks and higher ethanol oxidation rates than the controls. In 16 of these 17 subjects the mean blood alcohol peak was 127 mg/100 ml and the ethanol oxidation rate was 226 mg/100 ml/hr compared with 76 mg/100 ml and 161 mg/100 ml/hr, resp. for controls. The remaining alcoholic, a 71-yr-old man with gastritis who had drunk an average of 8 liters/day of wine (10% ethanol) for at least 50 yr, had a much higher initial blood alcohol level and blood alcohol peak than the others. No significant differences in liver alcohol dehydrogenase (ADH) activities, the ADH isoenzyme distribution, or plasma lipid fractions were found between alcoholics and controls. The most plausible explanation for these findings in alcoholics with normal liver function is a relative impermeability of cell membranes to alcohol. It is also suggested that the transformation of acetaldehyde into acetate may be increased in the cytoplasm of these subjects.

1498 PROLONGED ADMINISTRATION OF ETHANOL TO YOUNG, HEALTHY VOLUNTEERS: EFFECTS OF BIOCHEMICAL, MORPHOLOGICAL AND NEUROPHYSIOLOGICAL PARAMETERS. *(E.)* Belfrage, P.; Berg, B.; Cronholm, T.; Elmqvist, D.; Hagerstrand, I.; Johansson, B.; Nilsson Ehle, P.; Norden, G.; Sjovall, J.; Wiebe, T. (Dept. Physiol. Chem., Univ. Lund, Sweden). *Acta Med. Scand.* [*Suppl.*] 552:1-44, 1973.

1499 HEPATIC AND CARDIAC PROTEIN SYNTHESIS. ALCOHOL VS NUTRITION. *(E.)* Rothschild, M. A.; Schrieber, S. S.; Oratz, M. (VA Hosp., New York, N.Y.). *N.Y. State J. Med.* 73(24):2887-2890, 1973.

LIVER AND BILIARY TRACT

Cirrhosis

1500 HEPATIC BLOOD FLOW, PORTAL HYPERTENSION, AND LIVER FAILURE IN PATIENTS WITH ALCOHOLIC CIRRHOSIS. *(Fr.)* Lebrec, D.; Sicot, C.; Benhamou, J. P. (Beaujon Hosp., Clichy, France). *Arch. Fr. Mal. App. Dig.* 62(6):465-471, 1973.

Hepatic blood flow was measured with the indocyanine green technique in 37 chronic alcoholics, aged 36-64 yr, with cirrhosis and in 10 patients, aged 30-50 yr, with no evidence of portal hypertension or liver disease. Since the indocyanine green technique is subject to serious error when indocyanine green extraction is low, 10 patients with extraction values of 20% or lower were excluded from the study. Of the 27 remaining patients, 9 had end-to-side portocaval anastomoses and 8 others were studied before and after shunt surgery. Values for the plasma clearance and extraction of indocyanine green and hepatic blood flow were significantly lower in cirrhotics than in controls. Among the cirrhotics there was no significant correlation between the decrease in hepatic blood flow and the increase of the gradient between blocked and free subhepatic pressures or between hepatic blood flow and the presence of liver failure. Liver failure is arbitrarily defined as the persistence of jaundice and/or ascites and/or encephalopathy for more than 3 months, and/or a serum albumin concentration less than 30 g/liter, and/or a Quick time of more than 20 sec. No correlation was found between hepatic blood flow measured before shunt surgery and the development of liver failure one yr after surgery. The creation of a portocaval anastomosis had no appreciable effect on the gradient between blocked and free subhepatic pressure or indocyanine green extraction. The plasma clearance of indocyanine green hepatic blood flow were significantly decreased both before and after shunt surgery. No significant relation was found between hepatic blood flow measured 30-40 days after shunt surgery and the development of liver failure one yr after surgery. These findings indicate that there is no correlation between the decrease in hepatic blood flow and the severity of portal hypertension or liver failure. Measurement of hepatic blood flow before surgery is of no value in predicting whether surgery will benefit the patient. Shunt surgery does decrease hepatic blood flow, but there is no relation between the extent of this decrease and the benefit of surgery.

1501 ASSOCIATION OF SCLERODERMA, SJOGREN'S SYNDROME, AND PRIMARY BILIARY CIRRHOSIS. *(Fr.)* Levrat, M.; Descos, L.; Trepo, C.; Vandenput, F.; Lesbros, F.; Moulin, G.; Berthelemy, C. (Edouard Herriot Hosp., Lyon, France). *Arch. Fr. Mal. App. Dig.* 62(6):495-500, 1973.

A 56-yr-old woman with a 31-yr history of Raynaud's phenomenon presented with calcinosis cutis, Sjogren's syndrome, telangiectasias, and scleroderma. Chronic diarrhea was found to be caused by an abnormally large number of *Escherichia coli* in the small intestine whose growth was favored by histamine-resistant achlorhydria. Liver function tests were normal except for an increase in serum alkaline phosphatase activity. Three yr later the patient was hospitalized with signs of cirrhosis. On the basis of an increase in the antimitochondrial antibody titer and cholestatic changes found in a liver biopsy, a diagnosis of primary biliary cirrhosis was established. Tests for Australia antigen and lupus erythematosus cells were negative, but thyroid and parietal cell autoantibodies were found in the serum. These findings suggest that cirrhosis developed on a background of chronic hepatitis. Although some associations of cleroderma with primary biliary cirrhosis or Sjogren's yndrome have been reported in the literature, this s believed to be the first report of a patient with ll three of these conditions.

502 ROLE OF A FALSE NEUROTRANSMITTER, OCTOPAMINE, IN THE PATHOGENESIS OF HEPATIC AND ENAL ENCEPHALOPATHY. *(E.)* Lam, K. C.; Tall, A. .; Goldstein, G. B.; Mistilis, S. P. (Roy. Prince lfred Hosp. Camperdown, Australia). *Scand. J. astroenterol.* 8(6):465-472, 1973.

he role of false neurotransmitters in the pathoenesis of hepatic encephalopathy was investigated y assay of octopamine in the serum and urine of 25 atients. Serum levels and urinary excretion of ctopamine were elevated in all patients with hepatic ncephalopathy. There was a statistically signifiant correlation between the degree of encephalopathy nd serum and urine octopamine values, and in 10 paients with hepatic encephalopathy studied on 2 or ore occasions, octopamine levels paralleled variaions in mental state. In patients with primary enal disease and no liver disease, renal failure er se caused elevations of urine and serum octopaine. In patients with liver disease with secondary mpairment of renal function, rising serum octopaine levels correlated significantly with decreasing lomerular filtration rate and maximal urine flow ate. Elevated levels of false neurotransmitters uch as octopamine seem to be an important factor in he pathogenesis of hepatic encephalopathy, but heir role in renal impairment secondary to liver isease remains undetermined.

503 LYMPHOCYTE TRANSFORMATION BY PHYTOHAEMAGGLUTININ (PHA) AND PURIFIED PROTEIN DERIVAIVE (PPD) IN PRIMARY BILIARY CIRRHOSIS: EVIDENCE F SERUM INHIBITORY FACTORS. *(E.)* Macsween, R. N. .; Thomas, M. A. (West. Infirm., Glasgow, Scotland). *lin. Exp. Immunol.* 15(4):523-533, 1973.

actors inhibitory to lymphocyte transformation *in itro* by phytohaemagglutinin (PHA) and purified rotein derivative (PPD) have been demonstrated in he majority of sera from 11 patients with primary iliary cirrhosis. These factors inhibited transormation in response to PHA both of autologous ymphocytes, and of 'reference' lymphocytes, obained from a single donor, a healthy medical member f the laboratory staff known to be strongly Manoux positive. 'Reference' lymphocyte transformaion in response to PPD was significantly less when ultured in sera from both primary biliary cirrhosis atients and control subjects than when cultured in B serum. The investigation suggests that in primary iliary cirrhosis there is an intrinsic impairment f lymphocyte responsiveness to PHA, and that, in ddition, extrinsic serum factors inhibitory of PHA ransformation are present.

504 CHOLIC ACID SYNTHESIS AS AN INDEX OF THE SEVERITY OF LIVER DISEASE IN MAN. *(E.)* cCormick, III, W. C.; Bell, C. C., Jr.; Swell, L.; Vlahcevic, R. Z. (Health Sci. Div., Virginia Commonwealth Univ., Richmond). *Gut* 14(11):895-902, 1973.

Bile acid pool size and kinetics were determined in 17 patients with cirrhosis and 11 patients without liver disease and correlated with the severity of liver disease as determined by a grading system which assigned numerical values to various clinical signs and laboratory results. The total clinical score and the patients were divided into two groups of advanced (7-18 points) or mild (1-6 points) cirrhosis. The clinical rating was then correlated with the various aspects of bile acid metabolism. Cholic acid synthesis was markedly reduced in the early stages of cirrhosis and continued to decrease with the advancement of the liver disease. There was an inverse correlation between synthesis of cholic acid and the severity of cirrhosis. Nine of the 10 patients with advanced cirrhosis and a very low cholic acid synthetic rate (average 68 mg per day) died within one to 13 months from the start of the study. Patients with mild cirrhosis also had significantly reduced cholic acid synthesis (average 152 mg per day) but they all were well and alive three to 23 months after the study. In contrast, chenodeoxycholic acid synthesis was not markedly affected in either patients with mild or advanced cirrhosis. There was also a high degree of correlation between the fractional daily turnover rate of cholic acid and the severity of liver disease. The fractional daily turnover rate of cholic acid was greatly reduced (50%) in patients with advanced cirrhosis. Deoxycholic acid was reduced in patients with mild cirrhosis and virtually absent from the bile of patients with advanced cirrhosis. Cholic acid synthesis is a sensitive indicator of the hepatocellular damage; chenodeoxycholic acid synthesis is relatively unaffected by cirrhosis. The selective alteration in cholic acid synthesis probably resides in a deficiency of one or more enzymes regulating the formation of the 3-keto, 7 alpha, 12 alphadihydroxy precursor of cholic acid.

1505 REGIONAL VARIATIONS IN HEPATIC BLOOD FLOW AND FUNCTION IN MAN. *(E.)* Strandell, T.; Erwald, R.; Kulling, K. G.; Lundbergh, P.; Marions, O.; Wiechel, K. (St. Erik's Hosp., Stockholm, Sweden). *Acta Med. Scand.* 194(3):215-218, 1973.

Four male patients were studied with regard to arterio-hepatic venous extraction of oxygen and Indocyanine Green dye (ICG). Two patients with alcoholic cirrhosis of the liver had an atrophic right and a hypertrophic left liver lobe. They also had higher extractions of oxygen and ICG over the right than over the left lobe, most pronounced for ICG. The two other patients, one with an extrahepatic biliary stasis and one with a chronic pancreatitis, had livers of normal size and configuration. They displayed no regional differences in extraction of oxygen, but one of them had a lower extraction of ICG over the right than over the left hepatic lobe. The findings in the patients with cirrhosis might be explained by regional variations in metabolic rate and hepatic cell function in relation to blood flow, and possibly also by shunts from the portal vein to the hepatic veins of the left lobe. Total hepatic blood flow cannot be estimated with sufficient accuracy by the Bradley technique in patients in whom the hepatic extraction of the substance used is low and large regional variations in extraction may occur.

1506 CIRRHOSIS FOLLOWING METHOTREXATE ADMINISTRATION FOR PSORIASIS. *(E.)*

Coughlin, G. P.; Henderson, D. W.; Reid, J. G.; Grant, A. K. (Queen Elizabeth Hosp., Adelaide, Australia). *Med. J. Aust.* 2(10):499-501, 1973.

The case history of a 52-year-old female who developed cirrhosis following the administration of methotrexate for psoriasis is presented. She received continuous methotrexate therapy for 3 yr varying from 2.5 to 7.5 mg daily. There was no past history of hepatitis; alcohol intake had been negligible. Liver biopsy revealed considerable distortion of hepatic architecture; portal tracts contained increased fibrous tissue, which linked adjacent triads and in some areas appeared to surround regeneration nodules. Fatty change was not present, stainable iron was not increased, and there was no evidence of malignant change. The appearances were consistent with micronodular cirrhosis. Methotrexate therapy was discontinued and a further assessment was made 6 months later. A second liver biopsy demonstrated moderate distortion of hepatic architecture by bands of fibrous tissue with a tendency to link adjacent portal tracts. Scattered chronic inflammatory cells were present. Regeneration nodules were present, but these were not uniform throughout the biopsy. This patient illustrates the development of severe portal fibrosis, with sufficient features for a diagnosis of cirrhosis. Six months after withdrawal of this drug there was no significant alteration in hepatic size or histological appearance. Biochemical tests of liver function, which were initially only mildly impaired, also showed no significant change after this period. It is considered that the patient may have permanent liver damage.

1507 IDIOPATHIC PORTAL HYPERTENSION, MANIFESTATION OF A MORE GENERALIZED VASCULAR DISEASE? CASE REPORT. *(E.)*

Stalder, G. A.; Burckhardt, D.; Bianchi, L. (Univ. Med. Polyclin, Basel, Switzerland). *Helv. Med. Acta* 37(4):281-290, 1973.

A case report is presented of a 39-yr-old patient with idiopathic portal hypertension. The histology of a blind liver biopsy and of 3 biopsies from the hepatic hilus during the performance of a portocaval shunt showed a regular lobular pattern of the liver tissue with some slightly enlarged portal tracts. The chest X-ray showed a heart of normal size and configuration; the elctrocardiogram was normal. On right heart catheterization, the liver wedge pressure was slightly elevated (12.5 mm Hg). The right ventricular pressure tracing showed an early-diastolic dip with plateau formation. The patient suffered repeated episodes of bleeding from esophageal varices and a side-to-side portocaval shunt was performed. During a second cardiac catheterization the only abnormal finding at rest was a slightly elevated end-diastolic pressure. The possibility of a correlation between the portal vein changes in idiopathic portal hypertension and pathological process of the endocardium is considered. Toxic substances resorbed from the intestine pass to the liver and could account for the mural changes in the portal vein branches. The resulting portal hypertension causes a collateral circulation leading splanchnic blood directly to the right heart by-passing the liver. Through the collaterals, the substance causing the modifications in the portal vein branches or other toxic or humoral substances could be responsible for the damage of the endocardium. The patient had close professional contact with the following chemicals which could be the causative toxic substances: vinyl-chloride, propyl-alcohol, tetrachlor-ethylene, trichlor-ethylene, hydrochinone, hexachlorcyclohexane, methylene-chloride, and frigenes. It is possible that the idiopathic portal hypertension is a manifestation of a rather generalized venous vascular process.

1508 LIVER INJURY WITH METHOTREXATE THERAPY FOR PSORIASIS. *(E.)*

Podurgiel, B. J.; McGill, D. B.; Ludwig, J.; Taylor, F.; Muller, S. (Mayo Grad. Sch. Med., Rochester, Minn.). *Mayo Clin. Proc.* 48(11):787-792, 1973.

Liver biopsies from 33 patients with severe psoriasis were reviewed and the findings correlated with methotrexate dosage schedules. There was a significant positive association with frequency of administration. Fibrosis and cirrhosis (found in 8 of 33 patients) occurred only in those taking methotrexate for more than 12 days per month. Of the 25 patients without these lesions, only 3 had methotrexate 12 days per month or more. These findings suggest that methotrexate may be significantly hepatoxic when given frequently, but the drug may be safely given weekly for a period up to 4 yr.

1509 HEPATIC BILIRUBIN TRANSPORT IN NORMAL AND CIRRHOTIC SUBJECTS BY COMPARTMENTAL ANALYSIS OF THE PLASMA CLEARANCE CURVE AFTER INTRAVENOUS LOADING. *(Fr.)*

Pirotte, J. (Baviere Hosp., Liege, Belgium). *Biol. Gastroenterol. (Paris)* 6(3):183-196, 1973.

Fasting plasma clearance of bilirubin was investigated in 18 patients with cirrhosis and in 24 normal controls after administration of unconjugated bilirubin (2 mg/kg i.v.). In both normal and cirrhotic subjects the plasma clearance curve for bilirubin was biexponential and consisted of a slow and rapid component. The most plausible model compatible with the equation derived for these curves is a 3-compartment model in which plasma bilirubin (compartment 1) is in reversible equilibrium with a hepatic receptor pool (compartment 2). Irreversible bilirubin clearance occurs from compartment 2 to a secretory hepatocyte compartment (compartment 3). This irreversible step is associated with intrahepatic conversion of nonconjugated into conjugated bilirubin. Depending upon whether the plasma extraction coefficient, *ke*, was normal or decreased, cirrhotics were divided into groups. All of those with *ke* values less than .009 had increased nonconjugated bilirubin levels, hile only 2 of the 12 had increased conjugated bili-ubin levels. These findings suggest that cirrhotics ith decreased plasma extraction of bilirubin may ave an impairment of conjugation and increased re-lux of unconjugated bilirubin from the liver towards he plasma.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

522 RADICAL SURGERY OF CARCINOMAS OF THE INTRAHEPATIC BILE DUCTS. *(Fr.)* Alexandre, . H.; Petite, J. P.; Germain, M.; Chevalley, J.; oilleux, F. (Broussais Hosp., Paris, France). *hirurgie* 99(6):356-363, 1973.

Case reports are presented for 2 patients who were successfully operated on for carcinomas of the intrahepatic bile ducts. Both a 64-yr-old man and a 57-yr-old man presented with obstructive jaundice, and liver biopsies showed the presence of cholestasis.

At laparotomy these patients had tumors near and at, resp. the junction of the 2 major bile trunks in the liver. In addition, the second patient had a large stone and a diverticulum in his gallbladder. No metastases were present in either case. The first tumor involved the cystic, but not the hepatic, duct and was removed by *en bloc* resection of the liver. The second tumor invaded the portal and periportal region, passed into the parenchyma, was accompanied by perineural infiltration, and caused thrombosis of the portal vein. In this case a left hepatectomy was performed, the gallbladder was removed, and the flow of bile was restored with a Y-shaped loop of jejunum. Histological examinations revealed that the first tumor was an epithelioma and the second, a clear cell adenocarcinoma. It is recommended that radical surgery be performed on patients with tumors of the intrahepatic bile ducts, provided that no metastases are present. Literature reports indicate that some patients have relatively long survivals, compared to those who undergo palliative surgery, and remain relatively free of pain. No follow-ups are reported for these 2 patients.

1523 THE EFFECT OF CHOLECYSTECTOMY ON BILE SALT METABOLISM. *(E.)* Pomare, E. W.; Heaton, K. W. (Roy. Infirm., Bristol, England). *Gut* 14(10): 753-762, 1973.

Isotopic bile salt studies were performed in 13 cholecystectomy patients and 10 matched controls using labelled taurocholate and deoxycholic acid. Cholecystectomy subjects had reduced pools of both primary bile salts, cholate and chenodeoxycholate, while the deoxycholate pool remained normal in size. As a result of these changes, the total bile salt pool was reduced to almost half its normal size and deoxycholate became the predominant bile salt. The half-life of taurocholate was reduced but, because its pool size was diminished, the daily synthesis of taurocholate remained normal. There was accelerated transfer of ^{14}C from taurocholate-24-^{14}C to its metabolites in bile, especially deoxycholate conjugates. In 4 subjects studied pre- and postoperatively similar changes occurred in all the above parameters. The bile salt pool circulated during fasting as well as during digestion. The consequences of this are increased exposure of bile salts to intestinal bacteria and hence increased bacterial degradation; continuous passage of the bile salt pool through the liver, and therefore continuous and presumably enhanced feedback inhibition of hepatic bile salt synthesis. The reservoir function of the gallbladder influences the size, kinetics, metabolism, and composition of the bile salt pool. It is concluded that no study of bile salt metabolism is complete without some assessment of gallbladder status.

1524 EFFECT OF ORAL CHENODEOXYCHOLIC ACID ON BILE ACID KINETICS AND BILIARY LIPID COMPOSITION IN WOMEN WITH CHOLELITHIASIS. *(E.)* Danzinger, R. G.; Hofmann, A. F.; Thistle, J. L.; Schoenfield, L. J. (Mayo Clin., Rochester, Minn.). *J. Clin. Invest.* 52(11):2809-2821, 1973.

Bile acid kinetics and biliary lipid composition were characterized in 6 women with gallstones before and after 6 months of oral therapy with chenodeoxycholic acid, an agent that induced dissolution of cholesterol gallstones in man. Over a dosage range of 1-4 g/day, absorption varied from 0.8 to 2.3 g/day. The chenodeoxycholic acid pool expanded two- to sixfold, and bile became composed predominantly (> 90%) of chenodeoxycholic acid conjugated chiefly with glycine. Cholic acid and deoxycholic acid pools decreased markedly, so that the total bile acid pool expanded much less, about twofold on the average. Cholic acid synthesis decreased in 5 of the 6 patients, consistent with negative feedback inhibition of cholic acid synthesis by chenodeoxycholic acid. In 4 patients whose bile was above or close to saturation with cholesterol, the bile became unsaturated; in 2 patients, whose bile was unsaturated, it remained so. In 5 patients with radiolucent gallstones, chenodeoxycholic acid therapy was continued after completion of kinetic and composition measurements; the stones decreased in size or dissolved entirely during the subsequent 6 to 18 months. Similar measurements of bile acid kinetics and biliary lipid composition were made before and after a 6-month period without medication in a control group of 6 healthy women; no changes occurred.

1525 DUODENAL OBSTRUCTION CAUSED BY GALLSTONES: REPORT OF SIX CASES. *(E.)* Printen, K. J.; Safaie-Shirazi, S. (Univ. Iowa Hosp., Iowa City). *Am. Surg.* 39(12):688-691, 1973.

Six case histories of duodenal obstruction caused by gallstone are presented. Characteristic symptoms and signs in these patients are bilious vomiting, distension in the epigastric area and its disappearance after each vomiting, a previous history of gallbladder disease, and roentgenographic findings of air in the biliary tree and absence of small bowel distension with a distended stomach. Three criteria are advocated: removal of the stone, removal of the fistulous tract and cholecystectomy, either in single or multiple staged procedures depending upon the condition of the patient and the experience of the operating surgeon.

1526 GALLBLADDER VOLUME AND CONTRACTILITY AFTER TRUNCAL, SELECTIVE AND HIGHLY SELECTIVE (PARIETAL-CELL) VAGOTOMY IN MAN. *(E.)* Parkin, G. J. S.; Smith, R. B.; Johnston, D. (General Infirm., Leeds, England). *Ann. Surg.* 178(5):581-586, 1973.

The resting volume of the gallbladder, and its contraction after a normal meal, were studied by means of oral cholecystography in patients with duodenal ulcer before operation, and in patients who were in good health more than 1 year after truncal, selective or highly selective (parietal-cell) vagotomy. Truncal vagotomy led to significant dilatation ($p < 0.01$) of the gallbladder. Selective and highly selective vagotomy, both of which preserve the hepatic vagal fibers, were not followed by dilatation of the gallbladder. Contractility of the gallbladder

s unimpaired after each of the 3 types of vago-
my. It is suggested that function of the biliary
act in man may be better after highly selective
gotomy than after truncal vagotomy.

27 MICRO-GALLBLADDER AND BILIARY CALCULI IN MUCOVISCIDOSIS. *(E.)* Rovsing, H.; Sloth,

(Rigshosp., Copenhagen, Denmark). *Acta Radiol.*
(5):588-592, 1973.

diologic examination of the biliary tract was per-
rmed in 41 cystic fibrosis patients (16 females and
males, aged 6 months to 23 yr). The gallbladder
s considered normal in size in 22 patients, in 17
llowing cholecystography and in 5 only after chole-
aphy. In 6 patients it was definitely abnormal in
ze. The small gallbladders were not related to
e relative size of the patients. The outline was
gular in all the gallbladders, including the micro-
llbladders, and all contracted normally after a
tty meal. Gallstones were present in 1 patient
d probable in a second. In 11 of the patients no
lling or only partial demonstration of the biliary
act was obtained. Occlusion of the main biliary
act was excluded as the serum bilirubin was normal
all patients. Whether absence of contrast filling
related to known liver lesion or to biliary tract
thology in cystic fibrosis remains doubtful. The
ten elevated values of transaminases and alkaline
osphatases could not be significantly correlated
abnormal cholecystography or cholegraphy.

28 A STEREOLOGICAL STUDY OF INTRAHEPATIC BILE DUCTS. 2. BILE DUCT PROLIFERATION IN SOME THOLOGICAL CONDITIONS. *(E.)* Jorgensen, M. (Univ.

st. Pathol. Anat., Copenhagen, Denmark). *Acta*
thol. Microbiol. Scand. [*A*] 81(5):663-669, 1973.

le duct proliferation in 5 pathological conditions
s investigated in a stereological study of intra-
patic bile ducts. One hundred sectioned bile
cts chosen at random from each case are drawn on
acing paper. The long diameter (l) and the short
ameter (w) of these profiles are measured in mm.
e axial ratio q = w divided by l is calculated
r each profile. The profiles are grouped accor-
ng to their shape (q). The resulting percentage
stribution of axial ratios is compared with the
eoretical distributions of different cylinder
apes. The proliferating ductules are not small
ort and blindly-ending tubes connected with the par-
chyme. Nor, in this reconstruction, do they seem to
shoots from the original ductal system in the
rtal tract. They form a network with several con-
ctions to the parenchyma. The ductules are flat-
ned. The direction of flatness does not have any
[illegible] orientation, but varies in the network.

29 THE GALLBLADDER AS A CONDUIT BETWEEN THE LIVER AND INTESTINE. *(E.)* Waddell, W.

; Grover, F. L. (Univ. Colorado Med. Ctr., Denver).
rgery 74(4):524-529, 1973.

aumatic injury in a 16-yr-old girl forced cancellation of a needed end-to-end suture of the distal common duct to the dilated left hepatic duct over a T tube, because tissue loss, scaring, and infection resulting from the injury made it impossible to bring the right and left ducts together. Instead, the right hepatic duct was anastomosed to the gallbladder. In 3 other patients (2 men and 1 woman, aged 40-52 yr) the gallbladder was anastomosed to the common hepatic duct for palliation of inoperable carcinoma of the pancreas. The method might also prove useful for hepatic transplantation. These anastomoses are relatively easy to perform for they are made large and no tension exists. Also, the right hepatic duct and the upper common hepatic duct are in juxtaposition to the gallbladder. It is felt that since the common bile duct immediately below the bifurcation is about as far from tumor in the head of the pancreas as an anastomosis can be placed, this should lengthen the interval between operation and tumor extension causing recurrent biliary obstruction. This method avoids using a cholecystoduodenostomy when a low entering cystic duct has been ligated, divided, or otherwise obstructed. No reverse flow through the cystic duct occurs, thus eliminating extrahepatic obstruction at the cystic duct level from rejection or infection. No tubes or drains are required. This procedure also has the advantage of allowing the proximal anastomosis to be made with 2 openings the same size with tissues of approximately the same thickness.

1530 A STEREOLOGICAL STUDY OF INTRAHEPATIC BILE DUCTS. 3. INFANTILE POLYCYSTIC DISEASE. *(E.)* Jorgensen, M. (Univ. Inst. Pathol. Anat., Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 81(5):670-675, 1973.

Liver tissue from 10 newborn infants, all stillborn or dying shortly after birth was studied by stereology to investigate the validity of the conception of the intrahepatic biliary system obtained from 2 reconstructions. In all the cases, both kidneys were considerably enlarged and transformed into cystic and spongelike structures. All the livers were grossly normal except one which displayed a multitude of cysts. One hundred sectioned bile ducts, chosen at random from each of the cases, were drawn on tracing paper. For each of the numbered profiles, the length (l) and the width (w) were measured in mm. For each profile, the axial ratio q=w divided by l was calculated. The percentage distribution of profile shapes (q) is compared with the distribution of known geometric shapes. The spread in distribution of axial ratios among the 10 cases is quite pronounced compared to that of normal liver ducts and bile duct proliferation. Ductal populations are composed primarily of straight cylinders and secondarily of a mixture of flat elliptical cylinders called ductal plates and of irregular tubular structures approximating the shape of circular cylinders. The 2 components show no preferential widths. The structures are dilated compared to normal ducts, but in a very variable manner, and cysts are rare. It is concluded that the mixture of different ductal shapes constitutes a characteristic entity.

1531 SPONTANEOUS ENTEROBILIARY FISTULAS. *(E.)* Safaie-Shirazi, S.; Zike, W. L.; Printen, K. J. (Coll. Med., Univ. Iowa, Iowa City). *Surg. Gynecol. Obstet.* 137(5):769-772, 1973.

Spontaneous enterobiliary fistulas present in 92 patients (70 females and 22 males, aged 60-79 yr) studied along with the signs and symptoms and modalities of therapy according to the type of fistula. Cholecystoduodenal fistula was present in 70 patients, cholecystocolic fistula in 10, cholecystogastric fistula in 5, choledochoduodenal fistula in 4, and cholecystocholedochal fistula in 3. The majority of patients suffered pain in the right upper quadrant, nausea, vomiting and fatty food intolerance. Diarrhea was the major complaint of 3 of 10 patients with cholecystocolic fistulas and significant weight loss occurred in 3 of 5 cholecystogastric fistula patients. Of the 92 patients, 40 had gallstone ileus; all 40 had cholecystoduodenal fistulas. Of the remaining 52 patients, 47 underwent operation: 45 had a cholecystectomy and repair of fistulas; 2 had operations to control duodenal ulcer disease. Small contracted gallbladders were present in 45 patients with stones in 31. Multiple stones were found in 19 of 25 patients who underwent common bile duct exploration. Cholangitis was present in 16, biliary cirrhosis in 10. The overall mortality rate was 15.2%. Operative mortality rate was 13%. Patient histories included reports from 87% of these patients concerning 2 to 10 previous episodes of pain in the right upper quadrant from 6 months to 20 yr prior. Jaundice had been present in 32 patients previously and was present in 48 at admission. Air or barium in the biliary tree was found in only 31 of these 92 patients. It is suggested that this condition may be avoided by a more vigorous approach to cholecystitis and lithiasis.

1532 EFFECT OF DIETS WITH DIFFERENT FAT CONTENT ON THE BILE LIPIDS COMPLEX IN PATIENTS WITH CHRONIC HEPATITIS AND CHOLECYSTITIS. *(Rus.)* Beiul, E. A.; Shakhovskaia, A. K. (Inst. Nutrition, Moscow, USSR). *Vopr. Pitan.* (5):38-42, 1973.

GENERAL

554 VIRUS PARTICLES IN EPITHELIAL CELLS OF DUODENAL MUCOSA FROM CHILDREN WITH ACUTE ON-BACTERIAL GASTROENTERITIS. *(E.)* Bishop, R. F.; avidson, G. P.; Holmes, I. H.; Ruck, B. J. (Roy. hildren's Hosp., Melbourne, Australia). *Lancet* 7841):1281-1283, 1973.

lectron microscopy of duodenal mucosa from 9 children, aged 4 to 31 months, with acute nonbacterial gastroenteritis was used to reveal virus particles in pithelial cells. Duodenal biopsy was performed 7 to 120 hr after onset of symptoms of gastroenteritis. A repeat biopsy was performed 4 to 8 wk later n 3 of the children. Throat swab, duodenal contents, and stool specimen were subjected to routine ethods of culture for bacterial, fungal, and viral athogens. No bacterial or fungal pathogens were solated. The dissecting microscope revealed a atchy irregularity of the mucosal surface in most ases. Mucosal changes varying from mild to severe ere observed histologically in all 9 patients. The hanges included shortening and blunting of villi nd increased infiltration of the lamina propria ith mononuclear cells. Epithelial cells were more uboidal and less regular than usual. No vacuolation or cytoplasmic inclusion bodies were seen. In he electron microscope, viruslike particles were een in the epithelial cells of duodenal mucosa from of the 9 patients. Virus particles were recognized within distended cisternae of the endoplasmic eticulum in vacuolated cells. The morphological eatures of virus particles were identical in each f the 6 patients. Almost all particles had a ighly electron-dense core surrounded by a moderately ense capsid zone about 67 nm. in diameter. The 3 children who had a second biopsy after recovery revealed histologically normal duodenal mucosa.

1555 INTRACTABLE WATERY DIARRHOEA, HYPOKALAEMIA, AND ACHLORHYDRIA ASSOCIATED WITH NON-PANCREATIC RETROPERITONEAL NEUROGENOUS TUMOUR CONTAINING VASOACTIVE INTESTINAL PEPTIDE (V.I.P.). *(E.)* Fausa, O.; Fretheim, B.; Elgjo, K.; Semb, L. S.; Gjone, E. (Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 8(8):713-717, 1973.

A 60-year-old patient with a one-year history of intractable water diarrhea is described as having a typical 'WDHA-syndrome': watery diarrhea hypokalemia, and achlorhydria associated with non-beta-islet cell tumor of the pancreas. She was cured after removal of a non-pancreatic retroperitoneal tumor, histologically described as a complex ganglioneuroma. Preoperatively there was a high urinary excretion of catecholamines. The tumor contained a gastric secretory inhibitor demonstrated by bioassay, and by a specific radioimmunoassay high tumor content of vasoactive intestinal peptide (V.I.P.) was found. This observation strongly supports the concept of neural crest origin of the hormone-producing cells.

1556 NEONATAL NECROTIZING ENTEROCOLITIS. *(E.)* Master, S. P.; Truscott, D. E.; Templeton, A. C.; Middlemiss, J. H. (Mulago Hosp., Kampala, Uganda). *Br. J. Radiol.* 46(552):1063-1069, 1973.

Twenty-six cases of neonatal necrotizing enterocolitis occurring in a teaching hospital in East Africa are reported. The salient clinical features were vomiting, often bilious, abdominal distension, and constipation. The onset was most often in the first week of life but could occur up to three weeks after birth. Radiology provided the best means of diagnosis and the radiological signs commonly seen were dilated intestinal loops with fluid levels. Gas in the bowel wall produced a granular or foamy appearance, together with linear gas streaks or a concentric "ring" picture. Pneumoperitoneum and portal vein gas were seen in a few cases. Information regarding blood, stool and peritoneal cultures for organisms was available for 17 patients. In only 7 patients were the cultures positive. In 3 patients blood and stools both grew E. coli. In another 3 patients, the stools alone yielded mixed growth of E. coli and haemolytic streptococcus. In one case blood culture was positive for pseudomonas. Autopsy was performed on 15 cases. All were slightly dehydrated and jaundiced. The serosa of the gastro-intestinal tract were normal except in the areas of gangrene that had perforated. The mucosa were ulcerated over considerable distances. The most frequently ulcerated site was the terminal ileum. In the absence of perforation conservative management yielded the best results. Early diagnosis was essential for successful treatment.

1557 RESPONSE OF MAN TO INFECTION WITH VIBRIO CHOLERAE. I. CLINICAL, SEROLOGIC, AND BACTERIOLOGIC RESPONSES TO A KNOWN INOCULUM. *(E.)* Cash, R. A.; Music, S. I.; Libonati, J. P.; Snyder, M. J.; Wenzel, R. P.; Hornick, R. B. (Univ. Maryland Sch. Med., Baltimore). *J. Infect. Dis.* 129(1):45-52, 1974.

The spectrum of illness and the immunologic response produced by cholera in 111 volunteers from the Maryland House of Correction were studied. The strains of *Vibrio cholerae* used were classical Inaba 569 B and classical Ogawa 395. An oral dose of 10^8 organisms in buffered saline was required to induce the diarrhea of cholera. When given with live organisms, $NaHCO_3$ lowered the infecting dose from 10^8 to 10^4 organisms. Clinical manifestations of infection varied from culturally positive formed stools to "rice water" diarrhea. Severe diarrhea did not have an explosive onset but rather progressively increased in volume during a 24-hr period. In 45% of cases the stool was positive for *V. cholerae* before the onset of diarrhea. Titers of vibriocidal antibody rose after diarrhea, peaked the second week after challenge, and rapidly fell during the next four weeks.

1558 CORRELATION BETWEEN MORPHOLOGICAL ALTERATIONS AND ENZYME ACTIVITIES IN THE MUCOSA OF THE SMALL INTESTINE. *(E.)* Berg, N. O.; Dahlqvist, A.; Lindberg, T.; Norden, A. (Univ. Hosp., Lund, Sweden). *Scand. J. Gastroenterol.* 8(8):703-712, 1973.

Correlations between morphological alterations and enzyme activities were performed on 233 small intestinal biopsies taken from 178 adult patients with various gastrointestinal complaints. Parallel analyses were made of morphology (mucosal surface by dissection microscope inspection, mucosal index, distance from top of villi to bottom of crypts over depth of the crypts, and cellular changes), of intestinal dipeptidases and of intestinal disaccharidases. A statistical study of the correlation between these parameters showed: 1) All enzyme activities were significantly correlated to the morphological findings. The L-alanyl-L-proline dipeptidase activity was the one that was most strongly correlated to the morphology score, followed by lactase. 2) In severely pathological intestinal mucosa the disaccharidase activities were much more depressed than the dipeptidase activities. 3) Sucrase and isomaltase were strongly correlated to each other, as glycyl-L-leucine and glycyl-L-valine dipeptidase activities, and L-alanyl-L-proline and L-glutamyl-L-proline dipeptidase activities. There was a significant increase of the disaccharidase activities from the proximal part (duodenum) to the middle and distal parts of the gut. The increase for the dipeptidase activities was less obvious and only significant for peptidylproline dipeptidase activity.

1559 MICROBIAL CONTAMINATION OF THE GUT: ANOTHER FEATURE OF MALNUTRITION. *(E.)* Gracey, M.; Suharjono; Sunoto; Stone, D. E. (Princess Margaret Child. Med. Res. Fdn., Perth, Australia). *Am. J. Clin. Nutr.* 26(11):1170-1174, 1973.

The microbial flora of the stomach and upper small intestine was studied in 21 malnourished Indonesian children with diarrhea and compared with that found in 21 Australian children of Caucasian extraction with a variety of alimentary disorders. In the Indonesian children, there was marked microbial contamination of the upper gastrointestinal tract with a wide variety of microorganisms including: *enterobacteria, Streptococci,* fecal-type bacteria, *Corynebacteria, Salmonella paratyphi B, Shigella* sp., *Staphylococci, haemophilus influenza, escherichia coli,* and *klebsiella* sp. In several patients there was significant overgrowth by *Candida* sp., and in several others large numbers of anaerobic bacteria were isolated. It is suggested that these microbiological abnormalities are related to the pathogenesis of diarrhea in children with malnutrition.

1560 EPITHELIAL TUMORS OF THE SALIVARY GLANDS CONTAINING LYMPHATIC TISSUE. II. MIKULIEZ'S DISEASE. *(Pol.)* Sikorowa, L. (Inst. Onkol., Warsaw, Poland). *Patol. Pol.* 24(1):27-45, 1973.

GENERAL

Parasitology

1588 THE EPIDEMIOLOGY OF ANCYLOSTOMIASIS ON SAN MATEO ISLAND, CORRIENTES, ARGENTINA. *(Sp.)* Borda, C. E. (San Juan Bautista Hosp., Santo Tome, Argentina). *Bol. Chil. Parasitol.* 28(1/2):19-23, 1973.

Stool examinations were performed on 86 of the 154 inhabitants of San Mateo Island, a humid subtropical island in the Rio Uruguay on the border between Argentina and Brazil. The subjects examined consisted of 45 females and 41 males, 64% of whom were less than 21 yr old. The eggs of *Necator americanus* were found in the stools of 81 (94.2%) of those examined; 90.2% of the males and 97.89% of the females were infested. The pH of the soil around the school and ranchos averaged 6.2 (4.9 to 7.5), which favors development of the free-living larval stage of this parasite. The population lives in mud huts with earthen floors which they share with domestic animals. Water is obtained directly from the river, and there are no sanitary facilities. Foci of infection were found near the houses, in shady places, and in fenced-in areas of vegetation which were natural latrines. The inhabitants of this island generally go bare-footed.

GENERAL

Regional Enteritis

602 TRYPTOPHAN CONCENTRATION IN SERUM OF
PATIENTS WITH REGIONAL ENTERITIS. ITS
OSSIBLE RELATION TO DEPRESSION. PRELIMINARY RE-
ORT. *(E.)* Johansson, C.; Allgen, L. G.; Hell-
trom, L. (St. Erik's Hosp., Stockholm, Sweden).
cta Med. Scand. 194(6):551-552, 1973.

ryptophan concentration was studied in the serum
f 20 patients with regional enteritis. Very low
-tryptophan values were found in 3 patients who
ad recurrent disease with intestinal stenosis and
teatorrhea after ileal resections. Subnormal
alues were found in 2 patients with intestinal
tenosis and increased fecal fat excretion, and in
others without stenosis. Of 12 patients with
ormal S-tryptophan values, 4 had ileostomies, 3
f whom after extensive ilial resections. A con-
iderable fecal fat excretion was found in 2 of
hese patients. No patient with normal values of
-tryptophan had intestinal stenosis. Depression
as diagnosed in 4 cases. Three patients re-
orted improvement of depression and increased
orking ability during treatment for long periods
ith 0.6 to 1.2 g L-tryptophan/day. Withdrawal
f the medication resulted in a return of the
epressive symptoms. These results indicate that
lowered or sometimes very low serum level of S-
ryptophan in regional enteritis can be expected
patients with intestinal stenosis and steatorrhea.

1603 HISTOCOMPATIBILITY ANTIGENS IN PATIENTS WITH INFLAMMATORY-BOWEL DISEASE. *(E.)* Asquith, P.; Mackintosh, P.; Stokes, P. L.; Holmes, G. K. T.; Cooke, W. T. (Dept. Exp. Pathol., Univ. Birmingham, England). *Lancet* (7848):113-115, 1974.

The histocompatibility antigen phenotypes of 48 patients with ulcerative colitis and 56 patients with Crohn's disease were studied. In ulcerative colitis there was a significantly increased frequency of histocompatibility antigen 11 and 7 and a reduced frequency of antigen 3. In Crohn's disease the frequency of antigen 9 was significantly reduced. The differences in frequency of histocompatibility antigens found in ulcerative colitis and Crohn's disease suggest involvement of genetic factors in inflammatory-bowel disease and could be related to the patient's immunological reactivity. Certain histocompatibility phenotypes have been associated with specific diseases (celiac disease 1 and 8; Reiter's disease and acute anterior uveitis W27). In many of these conditions there is an increased family frequency, suggesting the involvement of genetic factors. The finding of altered frequency of certain histocompatibility antigens suggests that genetic factors were operating. An immunological hypothesis may explain the pathogenesis of inflammatory-bowel disease. Histocompatibility antigens may cross-react with viral or bacterial antigens, leading to immunological tolerance and hence undue susceptibility to the infectious agent.

1604 THROMBOCYTOSIS AND MYELEMIA IN CROHN'S DISEASE. (TWO CASES). *(Fr.)* Klepping, C.; Martin, F.; Duzer, A.; Villand, J. (no affil.). *Rev. Fr. Gastroenterol.* (87):35-52, 1973.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized complilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism, and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX		
SUBJECT INDEX		

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

SGOT	serum glutamic-oxalacetic transaminase
SGPT	serum glutamic-pyruvic transaminase
U	unit(s)
UV	ultraviolet
WBC	white blood cells (leukocytes), white blood count
yr	year(s)

NOTE

ue to circumstances beyond our control, *Gastroenterology Abstracts nd Citations*, Volume 7, Number 4, April 1973 inadvertently was mailed o another mailing list. We have arranged for additional copies to be rinted and mailed to the *Gastroenterology Abstracts and Citations* mailing ist. This should occur in the very near future.

e regret this inconvenience to our readers, and this office will ontinue surveillance to make sure that this issue will be mailed out orrectly as soon as possible.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

508 SELECTIVE MIGRATION OF LYMPHOCYTES WITHIN THE MOUSE SMALL INTESTINE. *(E.)* Parrott, . M. V.; Ferguson, A. (Western Infirm., Glasgow, cotland). *Immunology* 26(3):571-588, 1974.

actors which determine the migration of lymphoid ells to lamina propria or Peyer's patches of mouse mall intestine were investigated by autoradiographic racing of i.v. injected spleen, thymus, and lymph ode cells. The number of labeled cells found in ntigen-free grafts of fetal small intestine were ompared with numbers found in normally sited gut f syngeneic CBA and C3H/Bi mice. Thymus, normal pleen, and B spleen lymphocytes, labeled with (^{3}H)-denosine or (5-^{3}H)-uridine, were confined to Peyer's atches and closely associated villi in both normal nd grafted gut. (^{3}H)-Thymidine-labeled lymphoblasts rom the mesenteric nodes of young (19-22 days) inected with *Nippostrongylus brasiliensis* were found n the lamina propria of graft and normal small inestine, but (^{3}H)-thymidine-labeled lymphoblasts rom oxazolone-primed lymph nodes did not migrate o villi. These results indicate that cells from he right source will migrate to gut tissue in the bsence of intraluminal antigenic stimulus. Changes n receptors during differentiation may explain the ack of interest shown by lymphoblasts for nodular reas of the lymphoid tissue, but do not explain the rocess by which some cells extravasate into the amina propria and others do not. If a specific proess is involved it probably applies to both T and lymphoblasts.

609 GERMINAL CENTRES AND THE ORIGIN OF THE B-CELL SYSTEM. *(E.)* Nieuwenhuis, P.; van ouhuijs, C. E.; Eggens, J. H.; Keuning, F. K. Dept. Histol., Univ. Groningen, Netherlands). *Imunology* 26(3):497-507, 1974.

oung adult Gold-Agouti rabbits were subjected to 50 rads whole-body x-irradiation 1 week after ppendectomy or with the appendix shielded during rradiation. In control animals regeneration of ollicular structures in the spleen was observed 7 ays after irradiation; between the 7th and 14th day he number of cells/regenerating follicle and the umber of follicles increased rapidly. Follicular egeneration in appendectomized and irradiated anials was delayed for 3-4 days compared with controls, hile regeneration in the appendix-shielded and iradiated group was evident as early as 4 days postrradiation. Histologic examination showed complete bsence of germinal centers in appendixes of appenicostomized and irradiated animals. Local (^{3}H)-hymidine labeling of the appendix indicated subtantial cell traffic from the appendix to spleen ollicular structures, in particular to the lymphoyte corona and marginal zone, though not to germinal enters. Following challenge with paratyphoid vacine on the 10th day after irradiation, appendectoized animals had a substantially lower antibody esponse than did animals which had only been iradiated. Results for splenectomy 1 hr after antigenic challenge showed the spleen is essential to antibody formation. It is concluded that following 450 rads whole-body irradiation the appendix contributes to the recovery of antibody-forming capacity of the spleen by production of antibody-forming cell precursors; these latter cells are presumably identical with the folice-replenishing lymphocytes derived from appendix germinal centers.

1610 HISTOLOGICAL, HISTOCHEMICAL AND PHARMACOLOGICAL OBSERVATIONS ON MAST CELLS IN THE STOMACH OF THE RAT. *(E.)* Heap, B. J.; Kiernan, J. A. (Hlth. Sci. Ctr., Univ. Western Ontario, London, Canada). *J. Anat.* 115(3):315-325, 1973.

Gastric mast cells were examined in three strains of rat (albino Wistar, hooded Wistar, and Sprague-Dawley) by a variety of histochemical techniques. Mast cells with cytoplasmic granules containing sulfated mucosubstance were abundant in the extraglandular spaces of the superficial 2/3 of the gastric mucosa. These mucosal mast cells differed from the typical mast cells of the submucosal, muscular, and serosal layers in that (a) they were generally smaller; (b) they did not contain stainable hexoses in the α-D-arabinopyranoside configuration; (c) their granules did not owe any significant part of their acidity to carbohydrate-bound carboxyl groups; (d) histamine, detectable by the o-phthalaldehyde technique, was removed from mucosal, but not from typical mast cells by fixation in Carnoy and paraffin embedding. The mucosal mast cells were slightly more resistant than the typical ones to degranulation by compound 48/80 (*p*-methoxy-*N*-methylphenethylamine), administered for 5 days, and were completely degranulated by 5 days of treatment with dexamethasone. The latter drug had no effect on typical mast cells. The function of the gastric mucosal mast cells remains a mystery, but they may be involved in producing local vasodilatation and increased capillary permeability during periods of increased secretory activity.

1611 CHANGES IN PANCREATIC MORPHOLOGY ASSOCIATED WITH AGING. *(E.)* Kreel, L.; Sandin, B. (Northwick Park Hosp., Harrow, England). *Gut* 14(12):962-970, 1973.

Retrograde pancreatography has been carried out at necropsy in 120 cases and the results have been analysed in statistical detail. With increasing age, changes in pancreatic anatomy occur which must not be taken to indicate pathology. These changes are: (1) low or ptotic position of the pancreas so that the papilla of Vater is below the level of L3; (2) calcification of the splenic and superior mesenteric arteries which produce calcific densities around the pancreas; (3) increasing width of main pancreatic duct along its whole length at about 8% per decade; in the elderly, widths of 1 cm can occur in the main duct in the head of the pancreas without evidence of obstruction: (4) formation of ductular ectasia which affects mainly the interlobular ductules but also intralobular ductules; (5) some ectatic ducts reach the dimensions of cysts, ie, 1-2 cm in diameter. Other morphological changes which have been demonstrated and which may produce difficulties in radiological interpretation are: (a) narrowed ducts not due to stricture; (b) space-occupying lesions due to superior mesenteric artery, splenic artery, aorta, vertebral osteophytes, sympathetic ganglion, and lymph nodes; (c) metastases in the pancreas-these must be distinguished from primary pancreatic carcinoma. It is clear that the pancreas moves pari passu with the duodenal loop. This fact must be taken into account in isotope scanning of the pancreas in the elderly. The head of the pancreas may be entirely to the left of the spine in some cases. There is a steady increase in duct calibre with age throughout the whole of the pancreas. The normal dilated duct in the elderly retains its uniform tapering appearance with smooth margins, this is not so in obstruction or chronic pancreatitis. It is concluded that this study shows that definite changes occur in the pancreas with increasing age. These changes must be taken into account in assessing duct pancreaticograms if false interpretations are to be avoided.

1612 FINE STRUCTURE OF CYTOPLASMIC PARACRYSTALLINE IN HUMAN HEPATIC PARENCHYMAL CELLS. *(E.)* Ishihara, T.; Uchino, F.; Furutani, H.; Matsumoto, N. (Yamaguchi Univ. Sch. Med., Ube, Japan). *Acta Pathol. Jap.* 23(4):705-715, 1974.

Cytoplasmic paracrystalline structures were observed in hepatic parenchymal cells from a chronic alcoholic with hereditary sperocytosis and from a nonalcoholic with metastatic relapse of gastric cancer. The inclusions consisted of parallel filaments, 8-10 mμ thick and 15 nm apart, crossing each other at an approximate angle of 60° and forming a lattice-like structure. Such nonmembrane bound paracrystalline was located near the nucleus and corresponded to masses positively stained with the periodic acid-Schiff reaction. Most of the cytoplasmic paracrystalline was surrounded by a zone of cytoplasm containing increased granular endoplasmic reticulum and free ribosomes. The Golgi complex was also well developed. These organellar changes suggest that the cytoplasmic paracrystalline is a product of *de novo* synthes or storage, rather than a degeneration product of pre-existing organelles.

1613 ELECTRON MICROSCOPY OF ISOLATED RAT HEPATOCYTES BEFORE AND AFTER TREATMENT WITH PHALLOIDINE. *(Eng.)* Weiss, E.; Sterz, I.; Frimmer, M.; Kroker, R. (Vet. Pathol. Inst., Justus Liebig Univ., Giessen, Germany). *Beitr. Pathol.* 150(4): 345-356, 1973.

Isolated rat hepatocytes were studied before and after incubation with phalloidine (25 and 100 μg/ml cell suspension). Normal isolated hepatocytes were well preserved but had microvilli all over the cell surface and numerous autophagic vacuoles in various developmental stages. Vacuolization of hepatocytes, as seen in livers poisoned *in vivo* or *in situ*, did not occur in poisoned isolated cells. The inability of phalloidine to produce additional vacuoles in isolated hepatocytes gives further support to the theory that a hydrostatic pressure gradient is a prerequisite for vacuolization. After 10 min exposure to phalloidine most hepatocytes showed cytoplasmic bulges. It is suggested that these bulges result from structural changes of liver plasma membranes due to strong binding of the toxin. The structural changes then cause a "weakness" of the plasmalemma which yields to intracellular pressure, thus giving rise to the protusions and to the disintegration and death of the cells within 120 min of exposure.

1614 PROLIFERATION AND DIFFERENTIATION OF GASTROINTESTINAL CELLS. *(E.)* Lipkin, M. (Mem. Sloan-Kettering Cancer Ctr., New York, N.Y.). *Physiol. Rev.* 53(4):891-915, 1973.

1615 MAPPING OF THE SYMPATHETIC INNERVATION OF THE LEFT AND MEDIAN LOBES OF THE RAT LIVER. ELECTRON MICROSCOPIC STUDY. *(Fr.)* Blouin, A.; Cote, M. G. (Fac. Med., Univ. Montreal, Canada). *Rev. Can. Biol.* 32(3):187-211, 1973.

1616 STUDIES ON LIPIDS OF BRAIN, KIDNEYS, AND LIVER OF MICE DURING POSTNATAL DEVELOPMENT. *(E.)* Pushpendran, C. K.; Eapen, J. (Bhabha Atomic Res. Ctr., Bombay, India). *Biol. Neonate.* 23(3-4): 303-313, 1973.

1617 THE SYNTHESIS AND TURNOVER OF RAT LIVER PEROXISOMES. V. INTRACELLULAR PATHWAY OF CATALASE SYNTHESIS. *(E.)* Lazarow, P. B.; De Duve, C. (Rockefeller Univ., New York, N.Y.). *J. Cell Biol.* 59(2) Part 1:507-524, 1973.

1618 THE SYNTHESIS AND TURNOVER OF RAT LIVER PEROXISOMES. IV. BIOCHEMICAL PATHWAY OF CATALASE SYNTHESIS. *(E.)* Lazarow, P. B.; De Duve, C. (Rockefeller Univ., New York, N.Y.). *J. Cell Biol.* 59(2) Part 1:491-506, 1973.

1619 TWO EXAMPLES OF PHYSIOLOGICAL MATURATIONS IN RAT FETAL LIVER. *(E.)* Jacquot, R. L.; Plas, C.; Nagel, J. (Ctr. Biol. Developmental Biochem., Univ. Res. Ctr., Reims, France). *Enzyme* 15(1-6):296-303, 1973.

1620 THE REGULATION OF LIVER DEVELOPMENT BY BIRTH. *(E.)* Nemeth, A. M. (Med. Sch., Univ. Pennsylvania, Philadelphia). *Enzyme* 15(1-6): 286-295, 1973.

1621 CHANGES IN RAT LIVER MITOCHONDRIA AND ENDOPLASMIC RETICULUM DURING DEVELOPMENT AND DIFFERENTIATION. *(E.)* Pollak, J. K.; Duck-Chong, C. G. (Dept. Histol., Univ. Sydney, Australia) *Enzyme* 15(1-6):139-160, 1973.

522 MULTIHORMONAL REGULATION OF HEPATIC HISTIDASE DURING POSTNATAL DEVELOPMENT. E.) Feigelson, M. (Harlem Hosp. Ctr., New York, .Y.). *Enzyme* 15(1-6):169-197, 1973.

523 ULTRASTRUCTURE OF FETAL LIVER AT TERM AND DURING PROLONGED GESTATION IN THE RAT. E.) Thliveris, J. A. (Dept. Anat., Univ. Manitoba, innipeg, Canada). *Am. J. Obstet. Gynecol.* 118(6): 64-871, 1974.

624 AUTONOMIC INNERVATION OF THE TUNICA MUSCULARIS OF THE STOMACH AND INTESTINE. *(Rus.)* egosturova, Z. N. (no affil.). *Kazan. Med. Zh.* 5):74-75, 1973.

525 EMBRYONIC DEVELOPMENT OF BURSA OF FABRICIUS. *(Georg.)* Korkia, I. R. (Zool. Inst., revan, USSR). *Soobshch. Akad. Nauk Gruz. SSSR* 1(3):733-735, 1973.

ABSORPTION-EXCRETION-TRANSPORT

1646 EFFECT OF LUMINAL SODIUM CONCENTRATION ON BICARBONATE ABSORPTION IN RAT JEJUNUM. *(E.)* Hubel, K. A. (Univ. of Iowa, Iowa City). *J. Clinical Investigation* 52(12):3172-3179, 1973.

The influence of luminal sodium concentration (Na^+) on net bicarbonate (HCO_3-) absorption was studied by perfusing male Holtzman rat jejunum *in vivo*. When Na^+ was omitted from the perfusion fluid, HCO_3- absorption diminished by a fixed amount over a range of initial HCO_3- concentrations of 15 to 80 mM. This change was not caused by alterations in transmural electrical potential difference (PD) or direction of water movement. Because the rate of HCO_3- absorption decreased as the luminal HCO_3- concentration lessened, Na^+-dependent HCO_3- absorption accounted for an increasing percent of total absorption as the luminal concentration of HCO_3- diminished. The effect of Na^+ on HCO_3- absorption is mediated, at least in part, by H^+ secretion, because luminal CO_2 production (manifested by luminal P_{CO2}) dimished as HCO_3- absorption decreased. The changes in P_{CO}^2 are caused by reaction of H^+ with HCO_3- in the luminal fluid because luminal P_{CO2} is augmented by the presence of HCO_3- and is diminished by addition of phosphate or Tris buffer.

1647 DIBASIC AMINO ACID ABSORPTION IN MAN. *(E.)* Hellier, M. D.; Chir, B.; Holdsworth, C. D.; Perrett, D. (St. Leonard's Hospital, London, England). *Gastroenterology* 65(4):613-618, 1973.

Dibasic amino acid absorption in the human jejunum was studied through the use of a modified double lumen perfusion method. Kinetic constants (K_t and V_{max}) for lysine were: K_t 4.9 mM; V_{max} 51.3 µmoles min^{-1} 30 cm^{-1}; and for arginine were: K_t 3.8 mM, V_{max} 46.3 µmoles min^{-1} 30 cm^{-1}. Lysine absorption was compared in 4 normal and 4 cystinuric subjects. A significant difference was seen between these groups when studied by perfusion but not by using the oral load method. Furthermore, oral load studies using mixtures of lysine, ornithine, and arginine showed a difference between the groups for arginine but no difference for lysine and ornithine. All three dibasic amino acids appeared to be well absorbed in the cystinuric patients.

1648 STUDIES OF ANTI-INFLAMMATORY DRUGS AND ALIPHATIC ALCOHOLS ON ANTRAL MUCOSA. *(E.)* Cooke, A. R.; Kienzle, M. G. (Univ. of Iowa, Iowa City). *Gastroenterology* 66(1):56-62, 1974.

Studies were made in 4 dogs with antral pouches of transmucosal potential difference (PD), and Na^+, H^+, K^+, and Cl^- fluxes, in response to aspirin, phenylbutazone, indomethacin, and cortisone acetate, as well as the aliphatic alcohols of carbon chain lengths C_1 to C_4. Potential difference was measured using 3% agar-saturated KCl electrodes connected to a potentiometer. Net fluxes of electrolytes were measured after instillation of 15 to 20 ml of a solution of 100 mM HCl + 54 mM NaCl, plus the test substance. Aspirin, 10 mM and 20 mM, increased net gain of Na^+ into the pouch and increased net loss of H^+ from the pouch. The potential difference decreased from control of -43.8 mv to -31.2 mv in response to 20 mM aspirin. Phenylbutazone (200 mg per 100 ml), indomethacin (250 mg per 100 ml), and cortisone acetate (2.5 mg per 100 ml) did not change net movements of electrolytes or alter potential difference. The net movements of Na^+ and H^+ increased and potential difference decreased with the aliphatic alcohols (C_1 to C_4), and this effect was proportional to the molar concentration of the alcohol and to the carbon chain length; the greater the concentration or number of carbon atoms, the greater the effect. Branched chain alcohols (isopropanol nd *t*-butyl alcohol) had less effect on potential ifference and Na^+-H^+ movements than their straight hain counterparts. Hypertonic solutions of glucose aused a fall in potential difference and an increase n net Na^+-H^+ movements. Potential difference was ore sensitive of gastric mucosal damage than mea- urements of ion movement. These studies indicate hat the electrolyte and potential difference response f antral mucosa to alcohols and to anti-inflammatory rugs is generally similar to that found for fundic ucosa.

549 IRON IN THE DUODENAL MUCOSA OF NORMAL, IRON-LOADED, AND IRON-DEFICIENT RATS. *(E.)* attii, R.; Mielke, C. H., Jr.; Levine, P. Y.; rosby, W. H. (Boston City Hosp., Mass.). *Blood* 2(6):959-966, 1973.

ron absorption studies with oral $^{59}FeSO_4$ were per- ormed on 13 iron-depleted, 11 iron-loaded, and 10 ontrol male albino Sprague-Dawley rats, and nonheme ron was determined in both isolated epithelial ells and defoliated mucosa obtained from the duo- enum. Mean absorption by the control animals was 8.5% of the dose. Both iron-depleted and iron- oaded groups showed significant differences in iron osorption (54.5% and 2.2% respectively). Compared ith the normal controls, iron was decreased in the pithelial cells of the iron-deficient group, where- s higher concentrations were observed in the de- oliated mucosa of iron-loaded animals. The latter oservation was confirmed by the presence of iron- aden macrophages seen in sections of the lamina ropria of the iron-loaded rats.

550 INHIBITORY EFFECT OF KONJAC MANNAN ON BILE ACID TRANSPORT IN THE EVERTED SACS FROM AT ILEUM. *(E.)* Kiriyama, S.; Enishi, A.; Yura, . (Tokushima Univ., Japan). *J. Nutr.* 104(1):69-78, 974.

everal experiments were conducted to study the pos- ible mechanisms of the hypocholesterolemic effect f konjac mannan (KM) and to examine whether puri- ied, water-soluble, undenatured KM binds bile acids n an aqueous solution. Crude konjac mannan gran- les have a strong hypocholesterolemic activity in ats fed a hypercholesterolemic diet. The crude ranules are prepared from tubers of the Amorpho- hallus plant by removing starch and are composed ainly of konjac mannan which yields glucose and mannose lone on complete hydrolysis. The active principle n the crude granules was identified to be konjac annan itself. The rate of cholic acid or tauro- holate dialysis across a cellophane membrane was ot modified at all even when pure KM or pectin was dded at 0.25% (w/v) level to the cholic acid or odium taurocholate containing side (each concentra- ion, 0.1 mg/ml). Therefore, we concluded that KM r pectin binds neither of these acids in water, and onsequently, in the intestinal lumen. On the other and, it was shown using carboxyl-^{14}C-cholic acid nd sodium 24-^{14}C-taurocholate that bile acid trans- ort in the everted sacs prepared from the rat ileum, here the active transport capacity for bile acids localizes, was significantly lowered to 30 to 50% of the control values by the addition of KM (0.25%) to the mucosal medium. Citrus pectin did not show any inhibitory action at either level of 0.25 or 0.5%. The effective minimum concentration of KM seemed to be about 10^{-6} M. In the everted sacs from the proximal jejunum where the active transport machinery does not function, cholic acid transport activity was very low (about 10% or less of that in the ileum) and this diffusion process was not modified by the addition of KM.

1651 EFFECTS OF ETHANOL ON THE TRANSPORT OF MANGANESE BY SMALL INTESTINE OF THE RAT. *(E.)* Schafer, D. F.; Stephenson, D. V.; Barak, A. J.; Sorrell, M. F. (Univ. of Nebraska Med. Ctr., Omaha). *J. Nutr.* 104(1):101-104, 1974.

The transmural movement of manganese was measured in isolated loops of Sprague-Dawley rat jejunum and compared to that obtained when the perfusate on the mucosal side of the tissue contained 3% ethanol. In *in vivo* studies, fasted Sprague-Dawley rats were gavaged with 0.01 μCi ^{54}Mn in the presence of either water or ethanol solution (4 g/kg body weight). After 3 hours the livers were excised and counted for radioactivity. In the *in vivo* experiments, ethanol stimulated the absorption of manganese two-fold as measured by the uptake of this metal in the liver. In the *in vitro* experiments, ethanol stimulated the transmural movement of manganese by a factor of four. Pyrazole, an alcohol dehydrogenase inhibitor, reduced ethanol-induced transport of Mn by 70% in the perfused jejunum indicating that the effects of ethanol are principally mediated by metabolism of ethanol in the gut.

1652 THE EFFECT OF ATP ON THE TRANSPORT OF HEXOSES AND AMINO ACIDS IN EVERTED SACS OF RAT SMALL INTESTINE. *(E.)* Hardcastle, P. T. (Dept. Physiol., Univ. Sheffield, England). *Biochim. Biophys. Acta* 332(1):114-121, 1974.

The effects of exogenous ATP (5 mM) on the transport of hexoses and amino acids in everted sacs of rat small intestine were studied. Mucosal ATP was inhibitory to net leucine, glycine, and galactose transport whether expressed as mucosal transfer or final tissue concentration. The inhibition of transfer was specific to the ATP molecule; ADP, AMP, adenosine, or adenine produced no effect. The inhibitory effect of ATP could be prevented if additional Ca^{2+} or Mg^{2+} was present in the incubation medium. The divalent cations themselves had no effect on transport. ATP stimulated the efflux of leucine and galactose from preloaded preparations. The stimulatory effect was specific to ATP and could be prevented by extra Mg^{2+} in the incubation medium. Although ATP apparently inhibits intestinal transport by an increase in membrane permeability, the way in which ATP brings about the permeability change is not fully understood. ATP could act directly on the membrane due to its ability to chelate divalent metal ions or it could affect enzyme systems necessary to maintain structural integrity.

1653 ELECTROLYTE TRANSPORT ACROSS ISOLATED LARGE INTESTINAL MUCOSA. *(E.)* Binder, H. J.; Rawlins, C. L. (Yale Univ., New Haven, Conn.). *Am. J. Physiol.* 225(5):1232-1239, 1973.

Transmural electrolyte fluxes were determined across male, Sprague Dawley rat colonic mucosa stripped of its serosal and part of its muscular layer to determine the mechanism of ion transport in the large intestine. When 10 mM glucose was present in both mucosal and serosal solutions, the transmural electrolyte fluxes increased but the short-circuit current was not changed when compared to a glucose-free HCO_3-Ringer solution. Selective removal of Cl, HCO_3 or Na in the presence of glucose significantly decreased the transmural electrolyte fluxes. The fluxes, but not the short-circuit current were inhibited by acetaxolamide. These results are best explained by the presence of two Na-transport systems: an "electrogenic" and a "neutral" or coupled Na-Cl transport. It is proposed that the coupled NaCl absorption may represent two related ion exchanges: Na-H and Cl-HCO_3.

1654 AN AUTORADIOGRAPHIC STUDY OF THE INTESTINAL ABSORPTION OF ^{22}Na. *(E.)* Jodal, M. (Univ. of Goteborg, Sweden). *Acta Physiol. Scand.* 90(1):79-85, 1974.

The distribution of ^{22}Na within the villous tissue of 9 cats was studied by means of an autoradiographic technique during absorption of different saline solutions containing the tracer, the resolving power being about 10 μm. After the first minute of absorption most of the grains were localized in the epithelial cells, the grain density in the lamina propria being low. The same distribution of ^{22}Na was seen after 5 min incubation during maximal vasodilatation and during absorption of a hypotonic saline solution. A constant intraluminal perfusion of isotonic saline for 30 min changed the autoradiographic picture, the highest radioactivity concentration now being found in the lamina propria. The gradient of grain density along the villous length was, however, not as marked as that reported by Haljamae who proposed that this gradient was created by a countercurrent multiplication of sodium in the hairpin vascular loops in the villi. The results in this paper support the hypothesis that both sodium and water are crossdiffusing in such a system between the vessels constituting the countercurrent exchanger.

1655 EFFECTS OF OLEIC AND RICINOLEIC ACIDS ON NET JEJUNAL WATER AND ELECTROLYTE MOVEMENT: PERFUSION STUDIES IN MAN. *(E.)* Ammon, H. V.; Thomas, P. J.; Phillips, S. F. (VA Hosp., Wood, Wisconsin). *J. Clin. Invest.* 53(2):374-379, 1974.

To examine the effects of oleic acid and ricinoleic acid on jejunal absorption, steady-state jejunal perfusions were performed in 18 healthy volunteers, divided into 4 groups. Taurocholate, used to solubilize the fatty acids, did not influence absorption. Both fatty acids (concentration, 10 mM) reversed electrolyte and water net movement; that is, they induced fluid secretion; this effect was rapidly reversible. Ricinoleic acid (the active principle of castor oil) was the more potent, producing fluid secretion when perfused at concentrations at which oleic acid was without effect. However, ricinoleic acid was absorbed more slowly than was oleic acid, and hence was associated with higher intraluminal concentrations. Addition of lecithin and monoolein did not diminish the secretory effect of ricinoleic acid; addition of a secretory bile acid (taurodeoxycholate) did not enhance the effect. The response of the jejunal mucosa to a known cathartic provides observations pertinent to the pathophysiology of steatorrheal diseases in man. Dietary fatty acid also has secretory properties with respect to the human intestine; bacterial hydration, to hydroxy fatty acids, is not required to induce fluid secretion.

1656 EFFECT OF DIETARY CALCIUM AND AGE ON JEJUNAL CALCIUM ABSORPTION IN HUMANS STUDIED BY INTESTINAL PERFUSION. *(E.)* Ireland, P.; Fordtran, J. S. (Univ. of Texas Southwestern Med. Sch., Dallas). *J. Clinical Investigation* 52(11):2672-2681, 1973.

Jejunal calcium absorption was measured from test solutions containing 1.0, 2.5, 5, and 10 mM calcium (as calcium gluconate) in 2 groups of volunteer subjects: 7 adults, 22 to 31 yr old and 6 adults 61 to 75 yr old. Absorption rates increased progressively as luminal calcium concentration was increased, although there was a tendency toward saturation of the absorptive process at the higher concentrations. Calcium absorption was higher in normal young adults than in normal subjects over age 60. In both groups a 300 mg calcium diet for 4-8 wk enhanced calcium absorption relative to absorption rates after 4-8 wk on a 2,000 mg calcium diet. This adaptation was more definite and dramatic in the young than in the old subjects.

1657 THE EVERTED RAT INTESTINE USED AS A MODEL SYSTEM TO DEMONSTRATE REGULATION OF SODIUM ABSORPTION FOLLOWING HEMORRHAGE (37740). *(E.)* Martinson, I. M.; Ingraham, R. C. (Univ. of Minnesota, Minneapolis). *Proc. Soc. Exp. Biol. Med.* 145(1):21-24, 1974.

The everted intestine from male retired breeder rats (Holtzman strain) was used as a model system to demonstrate the regulation of sodium absorption following hemorrhage in dogs. Plasma obtained from dogs who had been hemorrhaged 20% of blood volume increased sodium absorption in the everted ileum segment of the rat. The plasma obtained from normovolemic dogs after angiotensin II was infused for 60 min caused a significant increase in sodium transport. Vasopressin was added to the serosal solution during the experimental hour to give a concentration equivalent to that found *in vivo* following a 20% hemorrhage. There were no consistent or significant changes in the movement of sodium. It is concluded that the experimental evidence supports the hypothesis that following contraction of the blood volume there is a change in the composition of the plasma that does significantly affect the absorption of sodium in an everted rat segment. This mechanism present in the intestine, then, should complement the role of the kidney in the homeostatic regulation of total body sodium.

1673 COMPARISON OF THE EFFECTS OF PROSTAGLANDINS E_1, E_2 AND OF HYPOVOLUMIC HYPOTENSION ON THE LOWER ESOPHAGEAL SPHINCTER. *(E.)* Goyal, R. K.; Rattan, S.; Hersh, T. (Baylor Coll. Med., Houston, Texas). *Gastroenterology* 65(4):608-612, 1973.

The effects of prostaglandin E_2 and A_2 on the lower esophageal sphincter pressure are studied in 2 lightly anesthetized opossums. Intravenous injection of these agents as a single bolus caused a dose-dependent fall in the lower esophageal sphincter pressure. Prostaglandin (PG) E_2 was as potent as PGE_1 whereas PGA_2 was much less potent than the E compounds. The threshold dose of PGE_2 was 0.15 μg/kg and maximal effect was found with a dose of 1 μg/kg. Threshold dose of PGA_2 was 1 μg/kg. All these prostaglandins caused a transient drop in the blood pressure. The effect on lower esophageal sphincter was much prolonged. The duration of the effect was related to dose; higher doses generally caused longer reductions in lower esophageal sphincter pressure. Hypotension produced by hemorrhaging and by intravenous injection of sodium pentobarbital produced no change in the lower esophageal sphincter pressure suggesting that fall in blood pressure is not related to fall in the lower esophageal sphincter pressure.

1674 COLONIC MOTILITY IN THE CAT. IV. PERIPHERAL PATHWAYS MEDIATING THE EFFECTS INDUCED BY HYPOTHALAMIC AND MESENCEPHALIC STIMULATION. *(E.)* Rostad, H. (Inst. Neurophysiol., Univ. Oslo, Norway). *Acta Physiol. Scand.* 89(2):154-168, 1973.

The peripheral pathways by which the hypothalamus and mesencephalon influence the motility of the colon were studied in 73 cats by combining brain stimulation and peripheral nerve sectioning, and by use of autonomic blocking agents. Excitatory colonic effects induced from the hypothalamic sympatho-inhibitory area with concomitant blood pressure falls were mediated through the sympathetic lumbar colonic nerves, whereas excitatory responses with associated blood pressure rises were conveyed through the latter as well as through the parasympathetic pelvic nerves. The augmentatory colonic effects usually associated with blood pressure rise evoked from the mesencephalon were conveyed through the colonic nerves only. The responses through the lumbar colonic and pelvic nerves were blocked by 4 mg/kg guanethidine and 0.5-1.0 mg/kg atropine, respectively. The augmentatory colonic responses from the hypothalamic sympatho-inhibitory area were blocked by 0.5-1.0 mg/kg of the beta-adrenergic blocking agent propranolol, whereas the effects from the other responsive hypothalamic areas, transmitted through the lumbar colonic nerves, were blocked by 2-4 mg/kg of alpha-blocker (phenoxybenzamine), but not by propranolol. This finding supports the presence of alpha-excitatory receptors in the colonic wall. Inhibition of colonic motility induced by hypothalamic and mesencephalic stimulation, were mediated through the lumbar colonic as well as through the splanchnic nerves. The effects were blocked by guanethidine, and those from the responsive hypothalamic zones were also blocked by propranolol.

1675 INTERACTIONS OF 5-HYDROXYTRYPTAMINE AND NARCOTIC ANALGESICS ON DOG INTESTINE IN VIVO. *(E.)* de Oliveira, L. F.; Sollero, L. (Dept. Pharmacol., Cidade Univ., Rio de Janeiro, Brazil). *Pharmacology* 10(5):291-297, 1973.

The effects of intra-arterially injected morphine and dextromoramide on 5-hydroxytryptamine induced contraction of the jejunum were studied in 38 mongrel dogs. Dextromoramide increased the intestinal contractile action of 5-hydroxytryptamine from 44.7 ± 8.8 cm H_2O to 154.6 ± 17.3 cm H_2O. This effect was reversible in about 15 min. The tryptamine antagonists LSD, BOL, dibenamine, and cyproheptadine failed in blocking 5-hydroxytryptamine and the narcotic analgesics. Atropine (50 μg/kg), however, was active in this respect. It is proposed that 5-hydroxytryptamine released by morphine acts on tryptamine receptors located on the ganglionar cells and is not blocked by LSD. Possibly morphine inhibits also the uptake of 5-hydroxytryptamine by the myenteric plexus which would explain the potentiation of exogenous 5-hydroxytryptamine.

1676 SOME CONTRACTILE AND ELECTROPHYSIOLOGICAL PROPERTIES OF THE EXTERNAL ANAL SPHINCTER MUSCLE OF THE CAT. *(E.)* Bowen, J. M.; Bradley, W. E. (Univ. of Minnesota Med. Center, Minneapolis). *Gastroenterology* 65(6):919-928, 1973.

The contractile properties of the external anal sphincter muscle of 13 cats were determined with the aid of a pressure-sensitive anal plug-transducer system. The mean contractile response of the indirectly stimulated sphincter was 52 mm Hg in cats anesthetized with 25 to 30 mg/kg sodium pentobarbital. Mean time from onset to peak of contraction was 45 msec for the sphincter response and 29 msec for the isometrically determined, contractile response of the tibialis anterior muscle in the same cats. Double contractile responses evoked by paired stimuli fused in the sphincter at longer stimulus intervals than in the tibialis anterior. These results indicate that the external anal sphincter is a slow twitch muscle. Complete paralysis of the tibialis anterior occurred before 50% block of the sphincter during constant infusion of 0.028 mg/kg/min tubocurarine. This difference in sensitivity is opposite that reported for slow twitch muscles, such as the soleus of the cat. The sphincter was more resistant to 0.056 mg/kg/min succinylcholine than the tibialis anterior. The sphincter was more susceptible to fatigue during tetanic stimulation than was the tibialis anterior. Distribution of action potentials evoked by unilateral indirect stimulation revealed that the sphincter is divided into right and left halves with end-plates concentrated in the region of the anal sacs. Miniature end-plate potentials were of the focal end-plate type, and were higher in amplitude, longer in time course, and slower in frequency than those recorded from the external intercostal muscle. True slow fibers were not present.

1677 REFLEX VAGAL INHIBITION OF ESOPHAGEAL MOTILITY. *(E.)* Abrahamsson, H.; Jansson, G. (Dept. Physiol., Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 89(4):600-602, 1973.

eflex vagal inhibition of esophageal motility was tudied in 7 cats. Distensions of proximal parts of he esophagus were made by transient inflation of a cm latex balloon. Mechanical stimulation of the harynx to induce swallowing was performed with a orceps. The right vagus nerve was cut at the cerical level and its distal end put on electrodes for lectric stimulation. The following drugs were iven: atropine 0.5 mg/kg i.v., guanethidine 3 to mg/kg i.v. and gallamine thriethiodide in repeated oses of 5 mg/kg. Distension of cervical or upper horacic parts of the esophagus produced a prompt eflex inhibition of lower esophageal motility whenver rhythmic contractions were present; it had no learcut effect on resting pressure in the absence f rhythmic contractions. The inhibition of the ower esophageal pressure waves induced by upper sophageal distension was unaffected by gallamine hriethiodide. The inhibitory lower esophageal esponse also persists after administration of guanethidine in a dose capable of eliminating reflex drenergic inhibition of gastric motility. The induced pressure waves are themselves eliminated by tropine, indicating that they are dependent on a holinergic vagal mechanism. Mechanical stimulation f the pharynx with associated swallowing movements nhibited motility in the lower esophagus in the ame manner as distension of the proximal esophagus. The study indicates that esophageal smooth muscles re controlled by a nonadrenergic, noncholinergic eural mechanism.

678 EFFECT OF TRUNCAL VAGOTOMY AND PYLOROPLASTY ON GASTRIC EVACUATION AND SMALL BOWEL PROPULSION IN THE RAT.

(E.) Nilsson, F. (Dept. Surg., Univ. Hosp., Uppsala, Sweden). *Acta Chir. Scand.* 139(3):731-734, 1973.

Truncal vagotomy and pyloroplasty, or pyloroplasty alone, were performed in albino Sprague-Dawley rats, and at the same time a tube was placed in the duodenum. After 1 week, radio-iodinated polyvinylpyrrolidone was given in test meals to the stomach and to the duodenum. Two labels (^{131}I and ^{125}I) were used simultaneously and given via an oro-gastric tube and the duodenal tube. Gastric evacuation and small bowel propulsion were estimated from the distribution of the activities. Gastric evacuation was retarded by vagotomy but small bowel propulsion was unaffected. Pyloroplasty did not change the fraction of activity evacuated from the stomach nor did it influence small bowel propulsion.

1679 MANOMETRIC STUDY OF THE UPPER ESOPHAGEAL SPHINCTER IN NORMAL SUBJECTS AND CHANGES IT UNDERGOES IN THE PRESENCE OF GASTROESOPHAGEAL REFLUX.

(Sp.) Benages, A.; Ridocci, M. T.; Civera, R. G.; Parrilla, P.; Cosin, J. A.; Molina, R.; Garcia-Conde Comez, F. J. (Fac. Med., Valencia, Spain). *Rev. Esp. Enferm. Apar. Dig.* 41(2):149-160, 1973.

Pressure at the upper esophageal sphincter was measured on 26 patients with radiologically confirmed disphragmatic hernia (17 with and 9 without gastroesophageal reflux), 6 patients who had undergone surgery for diaphragmatic hernia at least 1 month before, 1 patient with Zenker's diverticulum, and 30 normal controls. Under resting conditions the maximum mean pressure at the upper esophageal sphincter was significantly higher in patients with diaphragmatic hernia and gastroesophageal reflux (21.66 ± 8.7 mm Hg) than in controls (8.43 ± 2.65 mm Hg), but no appreciable difference was found between patients with diaphragmatic hernia and no evidence of reflux and the controls. Pressure values were normal in patients who had undergone surgery for diaphragmatic hernia. It is suggested that increased pressure at the upper esophageal sphincter found in patients with gastroesophageal reflux represents a response to the presence of irritants in the esophagus and may be a defense mechanism to prevent their passage into the pharynx and respiratory tract. During swallowing the ratio between the duration of the positive oropharyngeal wave and the negative component of the esophageal sphincter (before the onset of its active contraction) was equal to or greater than unity in all but 2 patients (1 with Zenker's diverticulum and 1 with diaphragmatic hernia and gastroesophageal reflux). This lack of pharyngosphincterian synergism may be a contributing cause to development of Zenker's diverticulum.

1680 CHANGES OF COLONIC MOTILITY DURING EXPERIMENTAL OBSTRUCTION.

(E.) Zlatarski, G.; Lynen, F. K.; Willmen, H. R. (Inst. Emergency Care, Sofia, Bulgaria). *Rendic. Gastroenterol.* 5(2):85-89, 1973.

Changes of colonic motor activity were studied in 33 dogs during complete obstruction using electromanometric procedures. The surface and frequency changes of the colonic waves were correlated and evaluated. The number, amplitude, and duration of waves and the duration of activity were also computed. The experiments were conducted on 3 groups: Group A (8 dogs), 6 and 36 hr measurements of normal colonic motor activity carried out in 2 different segments of the sigmoid, comparing obstruction to motility; Group B (7 dogs), 36 hr measurements in complete colonic obstruction aiming at establishing colonic motor activity changes in early and progressing obstruction; and Group C (18 dogs), at 48, 72, and 96 hr, following experimentally induced complete obstruction, relaparotomy and 6 hr measurements were carried out to detect changes of colonic motility in long standing obstruction. During obstruction, there was an increase in motility which reached its peak at 30 hr. After 72 hr, a new peak of activity occurred which, while not reaching the values of the thirtieth hr, followed a 2-peaked course. Up to the thirthieth hr, motor activity of the distal segment was greater; after the thirtieth hr, motility in the proximal segment had considerably higher values. There was no linear relationship between increase of circumference and motility increase during obstruction. Reduced motility recorded in the macroscopically intact distal segment is probably caused by the lack of bolus stimulation and by the obstruction induced disruption of excitation impulses in the colonic wall. Above the obstruction level, the distension of the colonic wall is paralleled by motility increase during 30 and 72 hr when the greatest activity was also recorded.

1681 THE EFFECT OF BRADYKININ ON INTESTINAL MOTILITY AND BLOOD FLOW. *(E.)* Fasth, S.; Hulten, L. (Univ. of Goteborg, Sweden). *Acta Chir. Scand.* 139(8):699-705, 1973.

The effect of bradykinin on motility and blood flow in the small intestine and the colon was studied in 41 anesthetized cats. When administered intravenously, bradykinin caused a profound intestinal inhibition and a concomitant increase in blood pressure. Adrenalectomy abolished these responses, thus indicating that they were caused by a secondary release of catecholamines from the adrenal medulla. Close intra-arterial bradykinin-infusion to the intestine caused an atropine-resistant motility increase and a blood flow increase. The threshold bradykinin dose concerning vasodilatation was about 10 times lower than that producing increased motility. High bradykinin doses produced a marked intestinal contraction and only a transient blood flow increase, the motility response interfering mechanically with the blood flow. With respect to the colon the vasodilator and motility responses to high does of bradykinin mimicked closely those induced by pelvic nerve stimulation, lending support to the hypothesis that a kinin-like mechanism might be involved in functional hyperemia in the colon.

1682 A NOVEL APPROACH TO THE QUESTIONS OF ALLOSTERIC PROPERTIES OR A 'RECEPTOR RESERVE' OF DRUG BINDING SITES OF INTESTINAL SMOOTH MUSCLE CELLS. *(E.)* Kuhnen-Clausen, D. (Inst. Aerobiol., Fraunhofer Soc., Grafschaft/Sauerland, Germany). *FEBS Lett.* 39(1):61-66, 1974.

SECRETION AND METABOLISM

99 RELATIONSHIP OF SERUM GASTRIN TO PARATHYROID HORMONE SECRETION IN SHEEP. *(E.)* affe, B. M.; Peskin, G. W.; Kaplan, E. L. (Washington Univ., Sch. Med. St. Louis, Mo.). *Metabolism* 3(4):307-310, 1974.

ne influence of hypergastrinemia on secretion of arathyroid hormone was studied in sheep. Synthetic iman gastrin 1 (4-9 µg/kg/hr) was infused i.v. for hr into fasted, unanesthetized sheep. Blood was otained at 14-min intervals before, during, and fter infusion of gastrin from an indwelling arteral catheter. Blood pH, serum total calcium and irculating gastrin and parathyroid hormone (radiommunoassay) were determined. Despite the fact that astrin infusion resulted in marked hypergastrinemia id in a small but statistically significant derease in total serum calcium concentration (mean nange in serum calcium 0.28 mg/100 ml), parathyroid ormone concentrations after gastrin infusions (34 Eq/ml) did not change from basal (35). These studes do not substantiate the suggestion that acute ypergastrinemia, directly or indirectly, results n the release of parathyroid hormone.

700 ANTRAL REACTIVITY: EFFECT OF VAGAL INNERVATION ON ANTRAL GASTRIN RELEASE BY ARIOUS STIMULI. *(E.)* Bombeck, C. T.; Soji, K.; abrys, B. F.; Nyhus, L. M. (Univ. of Illinois Med. tr., Chicago). *Am. J. Surg.* 127(1):76-82, 1974.

he effects of preservation of antral innervation on he hormonal physiology of the antrum were studied n 4 adult mongrel dogs. Initially, each dog underent standard parietal cell vagotomy of the main ody of the stomach. The second operation consised of construction of a standard Heidenhain pouch. uring saline infusion, pH 7.0, into the isolated ntral pouch at #100 ml/hr, no significant change as noted in the base-line levels of acid secretion rom the Heidenhain pouch. Vagal blockade did not ncrease the level of secretion, suggesting that he small degree of distention produced in the ouch by this method of irrigation was not signifiant in gastrin release and that vagal blockade id not augment antral distention by decreasing ntral muscular tone. When the antral pouch was rrigated with 2% liver extract, pH 7.0, a secretory esponse was regularly measurable from the Heidenhain pouch. Both the magnitude of a resultant rise in serum gastrin levels were highly variable. When the antral pouch was irrigated with 0.5% acetylcholine, thereby releasing endogenous gastrin, a prompt response was noted in the secretory volume and acidity of the Heidenhain pouch. Vagal blockade decreased acid secretion and at the same time resulted in a small increase in the serum gastrin level. Pentagastrin (0.5 µg/kg/hr) irrigation of the antrum produced the same level of stimulation as that noted with 0.5% acetylcholine. When the isolated antral pouch was irrigated with saline at pH 7.0 and a plateau of secretion was established with 0.5 or 0.25 µg/kg/hr of exogenous pentagastrin, significant inhibition of output from the Heidenhain pouch was noted by changing the antral pouch irrigant to 0.1 N HCl, pH 1.0. Most long-term follow-up studies of patients after parietal cell vagotomy have demonstrated the presence of residual basal acid secretion to a greater or lesser degree. That the reduction of acid secretion is sufficient to allow a duodenal ulcer to heal is the basis of this operative procedure.

SECRETION AND METABOLISM

Stomach

1707 ALTERATIONS IN SECRETORY PATTERNS FOLLOWING VAGOTOMY IN RATS WITH PAVLOV OR HEIDENHAIN POUCHES. *(E.)* Lundell, L.; Svensson, S. E. (Inst. Physiol. Univ. Lund, Sweden). *J. Physiol.* 234(3):703-721, 1973.

In conscious female Sprague-Dawley rats provided with Pavlov or Heidenhain pouches, the acid and pepsin secretion in response to feeding and i.v. infusion of gastrin was established before and after truncal vagotomy. In Pavlov pouches the responses to 2-deoxy-D-glucose, methacholine and the combination of gastrin and methacholine were also studied. Interdigestive secretion of acid and pepsin after vagotomy was decreased in the Pavlov pouch and increased in the Heidenhain pouch. The acid response to feeding in the Pavlov pouch was substantially reduced after vagotomy, whereas the secretion of pepsin was only slightly diminished. In the Heidenhain pouch after vagotomy, feeding augmented the high interdigestive secretion. After vagotomy, the acid dose-response curve to gastrin was shifted to the right in the Pavlov pouch and to the left in the Heidenhain pouch. In the Pavlov pouch after vagotomy, the acid response to the highest dose of methacholine (64 μg/hr) employed was significantly enhanced. A background infusion of methacholine (10 μg/hr) reestablished in the Pavlov pouch the reduced responsiveness to gastrin following vagotomy. Pepsin secretion was stimulated by gastrin in the Heidenhain pouch and after vagotomy in the Pavlov pouch. The stimulatory effect of methacholine on pepsin secretion in the Pavlov pouch was increased after vagotomy.

1708 EFFECT OF PARTIAL DEHYDRATION OF EX VIVO CANINE STOMACH ON SECRETORY FUNCTION. *(E.)* Kowalewski, K.; Jirsch, D. W.; Kolodej, A. (Surg.-Med. Res. Inst., Univ. Alberta, Edmonton, Canada). *Eur. Surg. Res.* 5(3):216-227, 1973.

Isolated whole canine stomachs were dehydrated for 4 hr then perfused *ex vivo* with homologous blood from living supporting dogs. Dehydration was produced by vacuum, during which temperatures fell to -3 C. During the perfusion period, the stomachs were stimulated intraarterially with histamine (150 μg/hr) and bethanechol chloride (500 μg/hr). The blood and gastric juice (30-min samples) were studied for various components. Perfusion lasted 6 to 8 hr. The secretory function of 7 dehydrated-perfused stomachs was compared with that of 7 stomachs perfused without prior preservation. Dehydration resulted in a loss of about 1/3 of the gastric tissue water. When the dehydrated, hypothermic stomach was connected with normothermic homologous perfusion blood, it regained its motility within 30 min and started to secrete H^+ and pepsin after a 30- to 90-min rest. After 5-8 hr of perfusion, all of the previously dehydrated stomachs regained their water content. The perfusion method used represents a model for assessing the functional viability of an organ preserved prior to transplantation. The viability and function of the parietal and chief cells of the gastric mucosa was retained despite prolonged anoxia and marked dehydration of the entire stomach.

1709 MARKED INHIBITION OF GASTRIC SECRETION BY TWO PROSTAGLANDIN ANALOGS GIVEN ORALLY TO MAN. *(E.)* Robert, A.; Nylander, B.; Andersson, S. (Upjohn Company, Kalamazoo, Mich.). *Life Sci.* 14(3):533-538, 1974.

Two prostaglandin analogs, 15(S)-15-methyl PGE_2, methyl ester, and 16, 16-dimethyl PGE_2 were administered to healthy, male volunteers, 22 to 30 years of age, for their possible effect in inhibiting gastric secretion. Both analogs, given orally, inhibited gastric secretion stimulated by pentagastrin, and the effect was dose dependent. The inhibition lasted for more than 4 hr, and no side-effects were noted at the doses used. When given intraduodenally, through a thin tube swallowed the night before, 15(S)-15-methyl PGE_2, methyl ester was more active than 16,16-dimethyl PGE_2. In view of their oral and prolonged activity, these analogs may have clinical potential in the treatment of peptic ulcer.

1710 EFFECT OF AN ELEMENTAL DIET ON GASTRIC SECRETION. *(E.)* Rivilis, J.; McArdle, A. H.; Wlodek, G. K.; Gurd, F. N. (Jewish Gen. Hosp., Montreal, Canada). *Ann. Surg.* 179(2): 226-229, 1974.

ne effect of an elemental diet on gastric acid
ecretion in the dog was studied. The diet contained
ubstantially the same amount of fat, protein and
arbohydrate as the dog food used in the control
eeds. Its composition (%w/v) was as follows: pro-
ein (equivalent in amino acids), 9.38; fat (20%
edium chain triglycerides), 14.29; carbohydrate
oy difference), 65.63. Vitamins and minerals were
resent in adequate quantities in the diet. Pavlov
ouches were constructed in anesthetized mongrel
ogs. Twelve control feeds were carried out with
10 g of Romar dog food. One day prior to the diet
xperiments, the dogs were fed only with the ele-
ental diet. Test meals of the elemental diet were
iven on the next 3 consecutive days. Two 15-min
ollections were made before all tests to ensure
ne dogs were secreting under basal conditions
nd then collections were made every 15 min for 3
r after each feed. The total 3-hr volume output
as reduced from control values of 47.46 ml to
).07 ml and the total 3-hr hydrogen output was
educed from control values of 6.17 mEq/liter to
.71 mEq/liter. After the first 15 min of feeding
nere was a marked reduction in both volume and
ydrogen ion output. As the hydrogen ion concentra-
ration decreased, the sodium concentration increased.
ne total 3-hr potassium and chloride outputs were
ignificantly diminished by the overwhelming drop
n secretory volume. The observed depression in
astric secretion could be the result of a reduc-
ion in the cephalic phase of gastric secretion or
y the reduced local stimulatory effects of the
redigested diet or both.

711 HISTOLOGY OF GASTRIC MUCOSA AND ITS SECRETORY ACTIVITY IN MAN. *(E.)*
arro, V.; Karacsony, G.; Pach, E. (Univ. Med. Sch.,
zeged, Hungary). *Acta Med. Acad. Sci. Hung.*
)(3-4):291-297, 1972.

ne histological picture of the fundic mucosa ob-
ained by blind biopsy was compared with the HCl
ecretory capacity of the same stomach in 144 male
nd 120 female clinical patients. HCl production
fter histamine injection was noticeably greater
n subjects with normal mucosa than in patients
ith different forms of gastritis. In the latter
ne production of HCl decreased parallelly with
ne severity of gastritis. The thickness of the
ctive parenchymal layer reflects the degree of
ne morphological and functional damage of the
ucosa more characteristically than do the values of
ne full thickness of the mucosa. The decrease in
ne number of active parenchymal cells follows the
everity of the morphological lesions. Among the
landular constituents, the chief cells seem to be
elatively most sensitive to progressive gastritis.

712 SYNTHESIS OF DOPA IN RAT STOMACH FOLLOWING INGESTION OF CEREALS. *(E.)* Hoeldtke, R.
.; Wurtman, R. J. (Dept. Nutr. Food Sci., Massachu-
etts Inst. Technology, Cambridge). *Metabolism*
3(1):25-31, 1974.

The cereal-containing chow routinely consumed by male Sprague-Dawley laboratory rats contains both free dihydroxyphenylalanine (DOPA) and an enzyme that catalyzes the conversion of tyrosine to DOPA. When tyrosine-^{3}H (1.8 μCi) was added to this food (0.5 g) and incubated for 2 hr, 1.26% of the tyrosine-^{3}H was converted to DOPA-^{3}H. When the tyrosine-^{3}H was incubated with the gastric contents from an animal that had ingested the rat food, 0.8% of the tyrosine-^{3}H was converted to DOPA. If the gastric contents were boiled prior to the incubation, or if the animals consumed a diet lacking cereals, little or no DOPA-^{3}H was synthesized. The 24-hr excretion of free and conjugated dihydroxyphenylacetic acid was much higher among animals ingesting the cereal-containing rat food than among rats whose diet contained casein as the sole protein source. These findings suggest that the tyrosine-hydroxylating enzyme in cereals continues to catalyze DOPA synthesis within the lumen of the rat stomach.

1713 EFFECT OF HISTAMINE AND ITS METHYL DERIVATIVES ON CYCLIC AMP METABOLISM IN GASTRIC MUCOSA AND ITS BLOCKADE BY AND H_2 RECEPTOR ANTAGONIST. *(E.)* Dousa, T. P.; Code, C. F. (Mayo Clin., Rochester, Minn.). *J. Clin. Invest.* 53(1):334-337, 1974.

In a cell-free system prepared from guinea pig gastric mucosa, histamine and N^α-methylhistamine produced dose-dependent stimulation of cyclic AMP formation and 1,4-methylhistamine had a minimal stimulatory effect. *N*-methyl-*N*'-(2-[5-methylimidazole-4-yl-methylthio]-ethyl)-thiourea (metiamide), a new H_2 receptor inhibitor, selectively blocked the stimulation of adenylate cyclase by histamine and its active methyl derivative but had no substantial effect on the basal adenylate cyclase activity or adenylate cyclase stimulated by sodium fluoride. Metiamide inhibited the histamine stimulation of adenylate cyclase at 1/100 the concentration of the histamine. Histamine, its methyl derivatives, and metiamide did not influence the activity of cyclic AMP phosphodiesterase from gastric mucosa. Therefore, histamine stimulates gastric mucosal adenylate cyclase via interaction with the H_2 receptor without influencing cyclic AMP breakdown and *N*-methylation of histamine on the side chain preserves or even increases its stimulating ability. *N*-methylation in the ring nearly abolishes the ability of histamine to interact with the H_2 receptor.

1714 THE RELATIONSHIP BETWEEN GASTRIC SECRETORY INHIBITION AND CEREBRAL AND GASTRIC LEVELS OF MONOAMINES IN PYLORUS-LIGATED RATS. *(E.)* Yamaguchi, I.; Katsuki, S.; Ohashi, T.; Kumada, S. (Fujisawa Pharm. Co., Osaka, Japan). *Jap. J. Pharmacol.* 23(4):523-534, 1973.

Neuroleptics, antidepressants, and minor tranquilizers, including chlorprothixene, octoclothepine, perphenazine, levomepromazine, chlorpromazine, haloperidol, molindone, desipramine, amitryptyline, imipramine, prazepam, chlordiazepoxide, pentolinium bitartrate, atropine sulfate, reserpine, tetrabenazine, tensibar, and DL-*p*-chlorophenylalanine, were compared quantitatively for their effects on gastric secretion in Shay rats and on barbiturate sleep in mice. It was shown that these 2 actions of neuroleptics are clearly related. The tricyclic neuroleptics, phenothiazines, chlorprothixene, and octoclothepine had the most potent antisecretory activity in centrally acting drugs, neuroleptics, antidepressants and minor tranquilizers. Centrally acting drugs all prolonged barbiturate sleeping time in mice in decreasing potency as follows: tricyclic neuroleptics, butyrophenones, benzodiazepines, antidepressants, and molindone. The anti-secretory action of neuroleptics and antidepressants was reduced in rats pretreated with reserpine (5 mg/kg, s.c.). Gastric secretion in Shay rats was clearly enhanced following a single injection of reserpine. The secretory volume and antisecretory activity of chloropromazine after reserpine returned to control levels concomitantly with the recovery of the cerebral levels of norepinephrine and serotonin and gastric levels of norepinephrine. Anti-secretory activity of imipramine and gastric levels of serotonin recovered more rapidly after reserpine treatment. It is postulated that the cerebral rather than gastric norepinephrine inhibits gastric secretion in Shay rats and is presumbaly involved in the antisecretory effect of chlorpromazine, and also possibly that of neuroleptics and antidepressants.

1715 EFFECT OF PARTIAL AND TOTAL VAGOTOMY ON THE GASTRIC ACID RESPONSE TO AN INSULIN INFUSION IN THE DOG. *(E.)* Dozois, R. R.; Kirkpatrick, J. R. (Dept. Clin. Surg., Univ. Edinburgh, Scotland). *Ann. Surg.* 179(1):12-16, 1974.

The effect of partial and total vagotomy on the gastric acid response to an insulin infusion was studied in 4 mongrel male dogs. Total vagotomy completely abolished, while partial vagotomy significantly reduced (57%) the acid response to an insulin infusion in the dog. The reduced acid response after partial vagotomy was noted to be graded with doses of insulin producing submaximal acid responses. These findings indicate that the stomach does not respond in an all-or-none fashion to vagal stimulation and support the notion of a segmental innervation of the parietal cell mass below the esophageal plexus.

1716 MANGANESE INDUCED HISTOCHEMICAL AND HISTOLOGICAL ALTERATIONS IN GASTROINTESTINAL MUCOSA OF GUINEA PIGS. *(E.)* Chandra, S. V.; Imam, Z. (Industrial Toxicol. Res. Ctr., Lucknow, India). *Acta Pharmacol. Toxicol.* 33(5/6):449-458, 1973.

Manganese-induced histochemical and histological alterations were studied in gastrointestinal mucosa of 70 male guinea pigs. Manganese chloride (10 mg/kg) was administered orally to guinea pigs for a period of 30 days. The histochemical and histological alterations in gastric mucosa consisted of loss of mucin and pepsinogen granules, adenosine triphosphatase and glucose-6-phosphatase activities and patchy necrosis of the epithelium. The intestinal villi also showed patchy necrosis, the activities of adenosine triphosphatase and glucose-6-phosphatase were diminished while there was an increase in the activity of acid phosphatase in the mucosa. Excess of manganese in the gastrointestinal tract produces functional and structural alterations in the mucosal cells. The exact mechanism of action needs further study. It is concluded that the loss of ATPase and glucose-6-phosphatase activity in the gastrointestinal mucosa in the experiments indicates impairment of metabolic activity of the cell under the toxic influence of manganese.

1717 INTERACTION OF NITRITE WITH PROTEINS AT GASTRIC pH. *(E.)* Knowles, M. E.; McWeeny, D. J.; Couchman, L.; Thorogood, M. (Food Res. Inst., Norwich, England). *Nature* 247(5439): 288-289, 1974.

The products obtained from the interaction of nitrite with bovine serum albumin under simulated gastric conditions are reported. The reaction was carried out in unbuffered solutions, the pH being adjusted initially to 2.5 and allowed to rise during the reaction to 4.0 to 4.5, thus simulating normal gastric pH changes during digestion. Bovine serum albumin (1 g) in dilute hydrochloric acid (10 ml; initial pH 2.5) was treated with sodium nitrite (0.069 g) in a stoppered flask, with stirring at 37 C for 2 hr. The resulting yellow solution was immediately dialysed and freeze dried. Weighed amounts of the pale yellow powder were hydrolysed with 6N hydrochloric acid under nitrogen. Acidic and neutral amino acids were analyzed automatically by ion exchange chromatography and peak areas were analyzed by computer. 3-Nitrotyrosine and dopa are identified from the reaction and are postulated to be degradation products of 3-nitrosotyrosine, and the ε-amino groups of lysine are deanimated to yield 6-hydroxynorleucine concurrently. This series of reactions shows that apart from nitrosamime formation, there are other nitrosation reactions involving nitrit in foodstuffs, which could take place under stomach conditions and yield modified amino acids.

1718 THE ACTIONS OF BOMBESIN ON GASTRIC SECRETION IN THE DOG AND THE RAT. *(E.)* Bertaccini, G.; Erspamer, V.; Impicciatore, M. (Inst. Pharmacol., Univ. Parma, Italy). *Br. J. Pharmacol.* 49(3):437-444, 1973.

The effects of bombesin, the tetradecapeptide occurring in the skin of the European discoglossid frogs *Bombina bombina* and *Bombina variegata variegata*, on the secretory activity of the stomach of the dog and rat are described. Bombesin stimulated acid secretion from the denervated fundic pouch of the dog. Whereas the concentration of hydrochloric acid in bombesin-produced juice was always higher than in control juice this did not occur for pepsin, the concentration of which remained below the basal values. The threshold dose of bombesin was 5-30 ng/kg by the s.c. route and 0.05-0.2 (μg/kg)/h by i.v. infusion. At low doses, bombesin was more active than caerulein, even on a molar basis, and at high dose levels was as active as caerulein. In contrast o gastrin and caerulein, bombesin elicited a oderate secretory response also following rapid i.v. njection. The acid secretion provoked by bombesin as almost completely inhibited by atropine and educed by approximately 50% by hexamethonium. ombesin did not stimulate acid secretion in the umen-perfused preparation of the rat stomach when dministered by s.c. injection (up to 10 μg/kg) r by i.v. infusion (up to 10 μg/kg hour). An rregular increase in acid output was observed nly following rapid i.v. injection and this was f doubtful significance. Preliminary experiments ave shown that both in dogs and man, gastric cid secretion elicited by bombesin was always ccompanied by a conspicuous increase of immunoeactive gastrin activity in plasma. This would point o the possibility that bombesin is a gastrineleasing factor.

SECRETION AND METABOLISM

Pancreas

723 PERFUSION OF THE ISOLATED PANCREAS IN THE DOG: COMPARISON OF THE EFFECT OF SECRETIN ND PANCREOZYMIN ON EXOCRINE PANCREATIC SECRETION. *Fr.)* Stock, C.; Stoebner, P.; Kachelhoffer, J.; renier, J. F. (Unit Exp. Surg. Biophysiopathol. ntestine, INSERM, Strasbourg, France). *Ann. Biol. lin. (Paris)* 31:377-385, 1973.

ancreatic enzyme secretion and ultrastructure were nvestigated in isolated dog pancreas before and fter intraarterial injection of secretin (30 U) and ancreozymin (25 U). Isolated pancreases were perused for 2.5 hr. Both secretin and pancreozymin mmediately increased the volume of pancreatic juice ecreted and the enzyme output. Secretin increased he volume of the juice to 30 times the control value nd pancreozymin, to 5 times the control value. Panreozymin increased amylase and lipase outputs to 0 and 12 times, resp., the control values, while ecretin produced only a 3-fold increase. Within 0 min of stimulation secretin caused 30% decrease nd pancreozymin a 50% decrease in the number of cells ith zymogen granules, but initial values were ttained again after 40 min. A progressive decrease n the number of zymogen granules occurred again uring the last 30 min of perfusion. It is conluded that both secretin and pancreozymin increase ancreatic enzyme secretion by stimulating release f zymogen granules into the lumen of pancreatic cini.

724 CHILD ABUSE AND TRAUMATIC PSEUDOCYST OF THE PANCREAS. *(E.)* Pena, S. D. J.; Medovy, H. (Dept. Paediatr., Univ. Manitoba, Winnipeg, Canada). *J. Pediatr.* 83(6):1026-1027, 1973.

Between 1958 and 1972, 13 children with proven pancreatic trauma were seen at the Winnipeg Children's Hospital. In 9 of these children, a pseudocyst of the pancreas was demonstrated, and 3 of these 9, child abuse was proven or strongly suspected. The case histories of the abused children, all under 3 yr of age, are presented. Blunt abdominal trauma accounts for at least half of the reported cases of pseudocyst of the pancreas in children. When a pseudocyst of the pancreas is found in children under 3 yr of age and no acceptable explanation for its occurence is forthcoming the possibility of child abuse should be considered.

1725 THE RELATIONSHIP BETWEEN CALCIUM EXCHANGE AND ENZYME SECRETION IN THE ISOLATED RAT PANCREAS. *(E.)* Case, R. M.; Clausen, T. (Arhus Univ., Inst. Physiol., Denmark). *J. Physiol.* 235(1): 75-102, 1973.

The role of extracellular and intracellular Ca^{2+} in pancreatic enzyme secretion was assessed by correlating the exchange of ^{45}Ca with amylase secretion in the isolated uncinate pancreas of baby Wistar rats. The rate coefficient of ^{45}Ca efflux from pre-loaded glands declined continually, indicating that ^{45}Ca is retained in several different pools and reflecting changes in the concentration of cytoplasmic free ^{45}Ca. The rate coefficient of ^{45}Ca release was not influenced by extracellular Ca^{2+} or Mg^{2+} concentrations.

Cholecystokinin-pancreozymin and acetylcholine acclerated the release of both ^{45}Ca and amylase in a dose-dependent fashion, but did not affect the initial rate of ^{45}Ca uptake by the tissue. In Ca^{2+}-free media basal amylase secretion slowly declined and stimulated secretion was abolished, but the accelerated release of ^{45}Ca was maintained. Thus, natural stimuli of pancreatic enzyme secretion alter cellular ^{45}Ca distribution independent of extracellular Ca^{2+} and in association with amylase secretion if the plasma membrane is not depleted of Ca^{2+}. Secretin, glucagon and insulin did not influence ^{45}Ca release. Replacement of extracellular Na^+ by Li^+ increased the release of ^{45}Ca and amylase, but only in the presence of extracellular Ca^{2+}. Li^+-substitution also increased ^{45}Ca uptake. Hyperosmolarity accelerated ^{45}Ca release and amylase secretion. 2,4-Dinitrophenol accelerated ^{45}Ca efflux but not amylase secretion, indicating that a rise in cytoplasmic Ca^{2+} will not initiate secretion if energy metabolism is impaired. Cholecystokinin-pancreozymin slightly increased the rate coefficient of ^{42}K release, indicating a changed membrane permeability. The stimulation effects of cholecystokinin-pancreozymin and acetylcholine were suppressed during Na^+-substitution by Li^+. Thus, the Na^+ concentration gradient across the membrane is important in secretion. The primary action of cholecystokinin-pancreozymin and acetylcholine may be to increase the influx of Na^+ into the cell by changing membrane permeability. This would release Ca^{2+} from intracellular stores (probably endoplasmic reticulum), leading to a rise in Ca^{2+} concentration close to structures involved in enzyme secretion. Secretion then follows if the ATP is available and the plasma membrane is not depleted of Ca^{2+}.

1726 A MICROPUNCTURE INVESTIGATION OF THE WHOLE TISSUE MECHANISM OF ELECTROLYTE SECRETION BY THE IN VITRO RABBIT PANCREAS. *(E.)*

Swanson, C. H.; Solomon, A. K. (Harvard Med. Sch., Boston, Mass.). *J. Gen. Physiol.* 62(4): 407-429, 1973.

Micropuncture techniques have been used to examine electrolyte secretion by the *in vitro* New Zealand rabbit pancreas. The concentration profiles of the major secreted ions and digestive protein and the electrical potential profile within the pancreatic ductal system have been determined during spontaneous and secretin-stimulated secretion. The active transport of both Na and HCO_3 are the rate-controlling steps in primary secretion. Spontaneous secretion is produced primarily within the intralobular ducts. The anion composition of the primary secretion depends on the secretion rate with HCO_3 ranging from about 70 mEq/liter at low rates to about 110 mEq/liter at high rates. With secretin stimulation the smaller extralobular ducts also secrete and this extralobular secretion has a higher HCO_3 content than that of the intralobular secretion. In the main collecting duct the anion composition of the juice is modified further by Cl-HCO_3 exchange which appears to be a passive process depending on the average residence time of the juice in the main duct.

1727 INTRACELLULAR DISTRIBUTION OF CO-LIPASE AND FOLATE CONJUGASE IN THE RAT PANCREAS.

(E.) Arnesjo, B.; Erlansson, C.; Jagerstad, M.; Lindstrand, K. (Univ. Hosp., Lund, Sweden). *Scand. J. Gastroenterol.* 8(8):719-724, 1973.

The intracellular distribution of co-lipase and pteroylpolyglutamate hydrolase (folate conjugase) was studied, using isopycnic gradient centrifugation of rat pancreatic homogenates. By comparison with lipase, almost the same proportions of co-lipase, but smaller proportions of folate conjugase, were recovered from the zymogen granule fractions. The specific activities (activity/mg protein) for lipase and co-lipase were high in the zymogen granules, but for folate conjugase the specific activity was high in the zymogen granules as well as in the cell sap. This study allows the following conclusions to be drawn. The similar distribution of lipase, measured by these 2 different methods, indicates that the cofactor for lipase, co-lipase, is present within all subcellular fractions in which lipase is found. Lipase and co-lipase are distributed in an almost similar fashion among the subcellular components of the rat pancreas. The folate conjugate is apparently localized within zymogen granules and the cell sap of the rat pancreatic exocrine cells. Rat pancreatic folate conjugase is most likely an enzyme which is secreted into the duodenum via the pancreatic juice.

1728 EFFECT OF LANTHANUM ON ^{45}Ca FLUX AND SECRETION OF PROTEIN FROM RAT EXOCRINE PANCREAS. *(E.)*

Heisler, S.; Grondin, G. (Dept. Pharmacol., Univ. Sherbrooke, Quebec, Canada). *Life Sci.* 13(7):783-794, 1973.

The relationship between calcium flux and secretion of protein from female Sprague-Dawley rat exocrine pancreas was studied. The trivalent cation La^{3+} was used to measure ^{45}Ca uptake. Carbachol increased the uptake of ^{45}Ca into the tissue prior to onset of secretion of α-amylase. La^{3+} inhibited ^{45}Ca uptake in carbachol-stimulated tissue, and also inhibited secretion of protein from the pancreas. Carbachol increased the rate of efflux of ^{45}Ca from the pancreas independently of the presence or absence of La^{3+}. In the presence of La^{3+}, however, the net loss of ^{45}Ca from the tissue was reduced. The data suggest that La^{3+} inhibits ^{45}Ca influx into the pancreas and may additionally displace intracellular calcium.

SECRETION AND METABOLISM

Hepatobiliary Tract

33 INITIATION OF FREE RADICAL REACTIONS AND
HEPATOTOXICITY IN RATS POISONED WITH CARBON
TRACHLORIDE OR BROMOTRICHLOROMETHANE[1]. *(E.)*
rdino, E.; Gravela, E.; Ugazio, G.; Vannini, V.;
lligaro, A. (Inst. Gen. Pathol., Univ. Torino,
aly). *Agents Actions* 3(4):244-253, 1973.

e effect of bromotrichloromethane on radical re-
tions in male Wister rats was compared with the
patotoxicity produced by carbon tetrachloride. The
ectron paramagnetic resonance signal and the UV-
ectrum of double bond shifting in microsomal lipids
ow that $CBrCl_3$ administration induces a more rapid
d extensive free radical reaction in liver than
l_4. More severe pathological phenomena are coin-
dent with a more profound pro-oxidant effect of
omotrichloromethane. In fact, 0.26 mmol of $CBrCl_3$
ove lethal after having caused massive fatty liver
d necrosis, while an equimolecular amount of CCl_4
duces a lower and transient hepatic triglyceride
cumulation and necrosis. Under the same experi-
ntal conditions, the lethal dose of carbon tetra-
loride is 20 times higher (5.16 mmol per 100 g body
ight). CCl_4-poisoned rats develop a remarkable
ssociation of liver polysomes. In animals given an
uivalent dose of $CBrCl_3$ these damages occur within
shorter lag period and are more severe. Moreover,
e recovery takes place much later than when carbon
trachloride is used. A clear inverse relationship
ists between the level of bond dissociation energy
these 2 halogenoalkanes (respectively, 49 and 68
al mol^{-1}, for $CBrCl_3$ and CCl_4) and their potency
stimulate free radical reactions and to produce
ver injury.

'34 ENZYMATIC CHARACTERISTICS OF CO-SENSITIVE
26-HYDROXYLASE SYSTEM FOR 5β-CHOLESTANE-3
,7α,12α-TRIOL IN RAT LIVER MITOCHONDRIA AND ITS
NTRAMITOCHONDRIAL LOCALIZATION. *(E.)* Taniguchi,
.; Hoshita, N.; Okuda, K. (Hiroshima Univ. Sch.
ent., Japan). *Eur. J. Biochem.* 40(2):607-617, 1973.

he enzyme characteristics of the mitochondrial 26-
ydroxylase system for 5β-cholestane-3α,7α,12α-triol
ere studied in rat liver mitochondria and the inner
embrane-matrix fractions with special attention to
ntramitochondrial localization. The study indicated
hat rat liver mitochondria, as well as microsomes,
possessed the hydroxylase system for 5β-cholestane-3α,7α,12α-triol as an intrinsic constituent. Product analyses revealed that only the mitochondrial hydroxylase system was specifically active for C-26 position. In contrast, the microsomal system was apparently unspecific on C-26 position but slightly more active for other adjacent positions. Among the tested citric acid cycle intermediates and nicotinamide coenzymes, isocitrate and NADPH exerted the most remarkable enhancement of the 26-hydroxylase activity. NADP and NADH were totally inert under the assay conditons. Partial rupture of the mitochondrial structure by hypotonic or digitonin treatment was essential for the reactivity of the 26-hydroxylase system, and it improved accessibility to the intramitochondrial reacting site of the exogenous reactants such as NADPH, isocitrate and 5β-cholestane-3α,7α,12α-triol in particular. The NADPH-dependent or isocitrate-dependent 26-hydroxylase system was insensitive to inhibitors of the respiratory electron transfer such as potassium cyanide, antimycin A, rotenone and amytal. However, it was specifically inhibited by phenyl isocyanide. The 26-hydroxylase system was remarkably sensitive to carbon monoxide. Apparent Michaelis constant for oxygen and partition coefficient (between carbon monoxide and oxygen) of the 26-hydroxylase system were estimated to be approximately 10-20μM and 0.1, resp. Thus, the possible functioning of a "cytochrome P-450"-like entity in intramitochondrial 26-hydroxylase system was proposed. The localization of 26-hydroxylase system was assigned to the inner membrane-matrix region, on the basis of the distribution of intramitochondrial marker enzymes during the course of serial solubilization by digitonin.

1735 CARBON TETRACHLORIDE INDUCED LIVER ALTERATIONS IN RATS PRETREATED WITH N,N'-DIPHENYL-p-PHENYLENEDIAMINE. *(E.)* Comporti, M.; Benedetti, A.; Casini, A. (Inst. Gen. Pathol., Univ. Pisa, Italy). *Biochem. Pharmacol.* 23(2):421-432, 1974.

Glucose-6-phosphatase activity of liver microsomes was decreased 15 min following carbon tetrachloride administration (0.25 ml/100 g by gastric intubation) to male Sprague-Dawley rats, but it was unaffected at 5 minutes. At the latter time, however, lipid peroxidation was already detectable in liver microsomal lipids. Pretreatment with N,N'-diphenyl-p-phenylenediamine (DPPD #3 i.p. doses of 60 mg/100 g) prior to CCl_4 poisoning did not prevent the peroxidation of microsomal lipids induced *in vivo* by carbon tetrachloride. Nor did it suppress the depression of glucose-6-phosphatase. Malonic dialdehyde production by liver homogenates or the microsome plus supernatant fraction was decreased by the addition of DPPD *in vitro* even at concentrations of 1.5×10^{-5} and 1.5×10^{-6} M. The *in vitro* pro-oxidant effect of CCl_4 was suppressed only when DPPD was present at the concentration of 1.5×10^{-4} M. Pretreatment of rats with DPPD significantly decreased the liver steatosis induced by carbon tetrachloride but did not prevent the fall in plasma triglyceride caused by the halogenated hydrocarbon. The effect of DPPD on the liver steatosis was manifested both when DPPD was administered in oil and when it was given as an aqueous suspension. In the former instance was DPPD found in appreciable amounts in the microsomal lipids, while in the latter case it occurred only in traces in the microsomal fraction. It is suggested that the ability of DPPD to decrease CCl_4-induced liver triglyceride accumulation is not related to an action of DPPD on the membranes of the endoplasmic reticulum of the liver cell.

1736 LIVER MICROSOMAL HYDROXYLATION OF STEROID HORMONES AFTER ESTABLISHING AN INDIGENOUS MICROFLORA IN GERMFREE RATS.

(E.) Einarsson, K.; Gustafsson, J. A.; Gustafsson, B. E. (Karolinska Inst., Stockholm, Sweden). *Proc. Soc. Exp. Biol. Med.* 145(1):28-52, 1974.

The liver microsomal metabolism of 4-(4-^{14}C)androstene-3,17-dione and 5α-(4-^{14}C)androstane-3α,17β-diol was studied in germfree, conventional and exgermfree rats with a normal indigenous microflora. Germfree rats were significantly more active than conventional rats in hydroxylating 4-androstene-3, 17-dione in positon 6β and 5α-androstane-3α, 17β-diol in position 2β, 7α and 18. In addition 7α-, 16α- and 16β-hydroxylation of 4-androstene-3,17-dione and 2α- and 7β-hydroxylation of 5α-androstane-3α,17β-diol tended to be greater in germfree rats than in conventional rats. In most cases the exgermfree rats, which had been reared outside the germfree isolators for 4 weeks, showed similar activities of the microsomal hydroxylase systems as their conventional counterparts. Thus, exgermfree rats showed significantly less efficient 16β-hydroxylation of 4-androstene-3,17-dione and 2β- and 7α-hydroxylation of 5α-androstane-3α,17β-diol than germfree rats. The results show that the induced state of certain microsomal hydroxylase systems in germfree rats is reversible and dependent on the metabolic changes in the germfree rat consecutive to the absence of the normal indigenous microflora.

1737 MASSIVE LETHAL HEPATIC NECROSIS IN RATS ANESTHETIZED WITH FLUROXENE, AFTER MICROSOMAL ENZYME INDUCTION.

(E.) Harrison, G. G.; Smith, J. S. (Dept. Anaesthetics, Univ. Cape Town, South Africa). *Anesthesiology* 39(6):619-625, 1973.

A group of 10 female Wistar rats were pretreated with phenobarbital (50 mg/kg/day, i.p.) for 3 days, and, on day 4, were anesthetized with fluroxene at a concentration of 3% in oxygen with a flow rate of 5 liter/min for 1 hr. This program was repeated 3 times. A second group received phenobarbital (80 mg/kg/day) for 3 days, and, on day 4, were anesthetized with fluroxene for 3 hr. After the first 1 hr exposure, 6 of the 10 rats in the first group died. All 10 rats in the second group died during or immediately after the 3 hr exposure to fluroxene. The livers were enlarged and showed massive central and midzonal necrosis. The remaining 4 animals from the first group, though sick after exposure, recovered and survived two further 1 hr exposures. Treatment with phenobarbital (50 mg/kg/day) increased cytochrome P450 levels by a factor of 1.5; phenobarbital treatment (80 mg/kg/day), by a factor of 2.6. No rat died in control groups anesthetized with fluroxene without enzyme induction, but the livers all showed demonstrable histologic changes, most notably a feathery degeneration of the cytoplasm with widespread vacuolation. These results indicate that fluroxene anesthesia in the rat in the presence of increased levels of hepatic cytochrome P450 caused a rapidly lethal fulminant hepatic necrosis and that fluroxene anesthesia alone caused histologic changes in the liver. Evidence to date suggests that it is some reaction in or metabolite resulting from the biotransformation of fluroxene which is the toxic agent. It is suggested that free radical formation or epoxidation of the vinyl radical of fluroxeneas a step in the transformation to carbon dioxide may take place and result in lipid peroxidation of the cell organelle membranes, leading to the observed massive cell destruction. It is urged that fluroxene anesthesia not be used for patients receiving drugs having enzyme-inducing properties.

1738 DIETARY REGULATION OF FATTY ACID SYNTHETASE AND MICROSOMAL GLYCEROPHOSPHATE ACYLTRANSFERASE ACTIVITIES IN RAT LIVER.

(E.) Wiegand, R. D.; Rao, G. A.; Reiser, R. (Dept. Biochem. Biophys., Texas A & M Univ., College Station). *J. Nutr.* 103(10):1414-1424, 1973.

The response of rat hepatic soluble fatty acid synthetase and microsomal glycerophosphate acyltransferase to qualitative and quantitative differences in dietary fat was studied. The effects on these enzymes of fasting and feeding after a fast were also studied. Fatty acid synthetase activities of livers of rats consuming either fat-free, 2.5% or 5.0% cocoa butter diet for 1 week were equal. However, 2.5% and 5.0% safflower oil diets reduced fatty acid synthetase activities by 25% and 40% respectively, and stock diet or fasting for 3 days reduced it 20% and 5%, respectively. Refeeding fat free 5.0% safflower oil or 5.0% cocoa butter for 2 days following a 3-day fast resulted in a 50- to 60-fold increase in fatty acid synthetase activity. Maximum activities of synthetase were reached between days 2 and 3 of refeeding regardless of the type of diet. Fat in the diet, saturated or unsaturated, did not inhibit this adaptive increase in fatty acid synthetase activity during the first few days. How-

er, at day 7 of refeeding there was a highly sig-
ficant drop in fatty acid synthetase activities
rats fed 5.0% safflower oil while that of those
d either fat-free or 5.0% cocoa butter remained
gh. Standard microsomal glycerophosphate acyl-
ansferase assay conditions were developed using
crosomes from rats maintained on a stock diet.
der these conditions the average specific activity
the acyltransferase was 5.2 nmoles phosphatidic
id synthesized per minute per milligram microsomal
otein. Glycerophosphate acyltransferase was not
gnificantly different after fasting for 3 days,
gestion of diets containing 2.5%, 5.0%, 10% and
% safflower oil or cocoa butter nor after stock or
t-free diets. However, refeeding the fat-free 5.0%
fflower oil or 5.0% cocoa butter diets for 2 days
llowing a 3-day fast increased its activity by
% over the prefasting or fasting levels. It re-
rned to the prefasting level between days 3 and 5
the refeeding period. These studies show that the
patic glycerophosphate acyltransferase activity
relatively constant while the fatty acid synthe-
se activity varies with qualitative and quantita-
ve dietary fat differences.

39 INFLUENCE OF DEHYDROCHOLATE ON HEPATIC
UPTAKE AND BILIARY EXCRETION OF ROSE BEN-
. IN THE RABBIT. *(E.)* Kelman-Sraer, J.; Erlin-
, S.; Peignoux, M.; Benhamou, J. P. (Hosp. Beau-
, Clichy, France). *Biomedicine* 19(9):415-418,
73.

e influence of sodium dehydrocholate on hepato-
iary elimination of radio-iodinated rose bengal
the rabbit was studied to determine the site
ere competition between bile acids and phthalein
es occurs. A compartmental analysis of the plasma
sappearance curve of ^{131}I-rose bengal after a
ngle injection was performed in a control group of
animals and in 2 groups of 6 animals receiving
ydrocholate infusions (6 and 10 μmol/min/kg,
sp.). The results indicate that under dehydro-
olate infusions the fractional transfer rate of
I-rose bengal from the plasma to the liver was
gnificantly decreased. The fractional transfer
te of ^{131}I-rose bengal from the liver to the bile
s significantly increased. These modifications
re dose-dependent. These findings suggest that
mpetition between bile acids and rose bengal oc-
rs for uptake by the hepatic cells and that
erefore the uptake processes for the 2 compounds
e at least partly common. The results further
ggest that competition between bile acids and
se bengal does not occur for biliary excretion.
ere could be a stimulation of the biliary excre-
ry mechanism of rose bengal by dehydroxycholate
its metabolites).

0 ENDOGENOUS STEROID SULFATES AND GLUCURON-
IDES IN THE GALLBLADDER BILE FROM EARLY
MID-TERM HUMAN FOETUSES. *(E.)* Huhtaniemi, I.
ept. Med. Chem., Univ. Helsinki, Finland). *J.
locrinol.* 59(3):503-510, 1973.

e neutral steroids derived from their conjugates
a pool of bile from 20 human fetuses were analysed by gas-liquid chromatography and gas chromatography-mass spectrometry. No free steroids were found, however, 10 monosulfates, 12 disulfates, and 7 glucuronides were detected. Both saturated and unsaturated steroids of the C_{19}- and C_{21}- series were detected. The glucuronides of 5β-pregnane-3α,20α-diol, 5α-pregnane-3β,16α,20α-triol and 3α-hydroxy-5β-pregnan-20-one as well as the monosulfate of 16α-hydroxydehydroepiandrosterone were present in the highest concentrations. Other major components were the monosulfates of dehydroepiandrosterone, pregnenolone and 16 -hydroxypregnenolone and the disulfates of 5-androstene-3β,17α-diol, 3β,17β-dihydroxy-5-androsten-16-one and 5β-pregnane-3ξ,20α,21-triol. The total concentration of the monosulfate conjugates was 435 μg/100 g sample (wet weight), of the disulfates 363 μg/100 g and of the glucuronides 815 μg/100 g. Many of these compounds have been found in fetal liver and intestinal contents. Therefore, during early and mid-gestation the fetal liver is apparently already excreting many steroid conjugates through the biliary tract into the intestinal canal. As in other fetal compartments, considerable amounts of steroid sulfates were detected. However, the steroid glucuronides in the bile suggest that the formation of hepatic glucuronides already occurs during this period.

1741 STIMULATION OF TAURODEOXYCHOLATE 7α-HYDROXYLASE OF RAT LIVER BY ADENOSINE 3':5'-MONOPHOSPHATE AND SATURATED FATTY ACIDS. *(E.)* Prager, G. N.; Voigy, W.; Hsia, S. L. (Univ. Miami Sch. Med., Fla.). *J. Biol. Chem.* 248(24):8442-8448, 1973.

Tauro [24-^{14}C]deoxycholate was incubated with liver microsomes from male Sprague-Dawley rats to demonstrate 7α-hydroxylation of taurodeoxycholic acid. Following hydrolysis of the conjugated bile acids, radioactive cholic acid was identified as the major product of the reaction. The taurodeoxycholate 7α-hydroxylase system required NADPH and molecular oxygen for activity. The activity was inhibited by carbon monoxide and this inhibition could be reversed by light, suggesting cytochrome P-450 involvement. Addition of the 105,000 x g supernatant to the microsomes stimulated 7αhydroxylation of taurodeoxycholate. Cyclic adenosine 3':5'-monophosphate also stimulated the 7α-hydroxylation. However, the amount of the nucleotide present in the supernatnat fraction could account for only 30% of its stimulatory activity. The dialysate of the supernatant was fractionated, and the fraction containing fatty acids, but free of cyclic adenosine 3':5'-monophosphate also possessed also possessed stimulatory activity. Palmitic, stearic, and linoleic acids were the major fatty acids in this fraction. Saturated fatty acids with chain lengths of C_{12} to C_{20} stimulated, while long chain unsaturated fatty acids inhibited the 7α-hydroxylation. Saturated fatty acids reversed the inhibition by unsaturated fatty acids. The stimulatory effects of cyclic adenosine 3':5'-monophosphate and palmitic acid were additive when their concentrations were less than producing maximal stimulation. Maximal stimulation by either cyclic adenosine 3':5'-monophosphate, palmitate, or the supernatant fraction was comparable. The fatty acid content of the 105, 000 x g supernatant was sufficient to account for maximal stimulation.

1742 STUDIES ON THE ETHANOL-INDUCED DECREASE OF FATTY ACID OXIDATION IN RAT AND HUMAN LIVER SLICES. *(E.)* Blomstrand, R.; Kager, L.; Lantto, O. (Karolinska Inst., Stockholm, Sweden). *Life Sci.* 13(8):1131-1141, 1973.

Mechanisms involved in acute ethanol-induced liver triglyceride accumulation have been investigated. Oxidation, esterification, and β-keto acid formation were examined in male Sprague-Dawley rat and human liver slices after incubation with albumin bound, long chain fatty acids (palmitic, oleic, and linoleic acids). Alcohol added to rat and human liver slices depressed the formation of $^{14}CO_2$ from palmitic acid-1-^{14}C, oleic acid-1-^{14}C and linoleic acid-1-^{14}C. Esterification to triglycerides and phospholipids was increased and the formation of β-keto acids was decreased by alcohol. The alcohol effect on the lipid metabolism of the liver slices was almost prevented by 4-methylpyrazole. Therefore, oxidation of alcohol is obligatory for the decreased β-oxidation of fatty acids, the increased esterification and for the decreased formation of β-keto acids. The results suggest that ethanol oxidation inhibits β-oxidation of fatty acids and that this primary effect leads to accumulation of liver triglycerides by increased esterification of plasma free fatty acids. It is suggested that a high rate of ethanol oxidation may be a factor in the development of acute liver triglyceride accumulation.

1743 THE EFFECT OF PHENOBARBITAL ON CHOLESTEROL GALLSTONES IN HAMSTERS. *(E.)* Lagarriga, J.; Bouchier, I. A. D. (Roy. Free Hosp., London, England). *Gut* 14(12):956-961, 1974.

The influence of phenobarbital on bile chemistry and gallstone formation was studied in 70 male golden hamsters (Cricetus aureatus), aged 5 weeks. Phenobarbital (400 mg/kg/day) were administered to the hamsters that were receiving a diet known to induce cholesterol gallstones. After a 28-day period none of the control animals had gallstones whereas 5 of 12 animals with added phenobarbital developed stones. Ten of 19 animals on the lithogenic diet formed gallstones but when phenobarbital was added gallstones occurred in 16 of 19 hamsters. The administration of phenobarbital resulted in the production of bile which was relatively more saturated with cholesterol of 24.8 in control animals altering to 9.1 in animals receiving phenobarbital. Hepatic bilirubin uridine diphosphate-glucuronyl transferase activity was not increased in animals on phenobarital. It was concluded that, in the hamster at least, there is no indication that large doses of phenobarbital will reduce the potential for gallstone formation. Many variables will need to be considered before it can be established that phenobarbital will alter bile composition to favor dissolution of gallstones in man.

1744 ROLE OF HEPATIC BILE COMPOSITION IN GALLSTONE FORMATION IN BABOONS. *(E.)* McSherry, C. K.; Morrissey, K. P.; Javitt, N. B.; Glenn, F. (New York Hosp., N. Y.). *Ann. Surg.* 178(5):669-675, 1973.

The lipid composition of hepatic bile was studied in normal and gallstone-forming baboons to evaluate the role of cholesterol solubility in the pathogenesis of cholesterol gallstones. Both groups of animals secreted hepatic bile supersaturated with cholesterol. In cholecystectomized animals food intake, estrogens, corticosteroid (methylprednisolone), and the oral ingestion of cholesterol and lecithin failed to exert a significant effect on the lipid composition or cholesterol solubility of hepatic bile. Bile salt administration in the form of sodium taurocholate increased bile salt excretion by the liver into hepatic bile with concomitant increase in the solubility of cholesterol. A distinction was made between basal and stimulated hepatic bile flow. Basal bile flow is the type of bile secreted by the liver after 90% of the bile salt pool has returned to the gallbladder. Stimulated bile flow occurs during the reabsorption from the intestines and secretion into bile of 90% of the pool. In the former, cholesterol is present in the supersaturated state whereas in the latter it is less than saturated. Following removal of the gallbladder, bile salt absorption from the gastrointestinal tract and secretion by the liver into hepatic bile is constant and the lipid composition of hepatic bile resembles stimulated bile flow. The efficacy of cholecystectomy in interrupting the course of calculous biliary tract disease is explained by the change in hepatic bile flow from alternating basal and stimulated bile flow to a state of constant stimulated flow.

1745 INFLUENCE OF CLOFIBRATE (ETHYL-4-CHLOROPHENOXYISOBUTYRATE) ON HEPATIC DRUG METABOLISM IN MALE RATS. *(E.)* Lewis, N. J.; Witiak, D. T.; Feller, D. R. (Coll. Pharm., Ohio State Univ., Columbus). *Proc. Soc. Exp. Biol. Med.* 145(1):281-285, 1974.

Elevations in liver weight, liver/body weight, and microsomal protein content associated with chronic clofibrate administration in male albino Harlan Wistar rats were found to be dependent upon the age of the animals. Pretreatment with clofibrate significantly reduced pentobarbital and zoxazolamine sleeping times in a dose-dependent manner and enhanced the rates of microsomal metabolism for pentobarbital, ethylmorphine and aminopyrine. Specific activities of microsomal enzymes involved with the hydroxylation of zoxazolamine or aniline remained unaffected via chronic drug administration. The metabolism of all drug substrates were significantly increased via pretreatment with clofibrate when the results were expressed on the basis of total liver protein. The microsomal rates of ethylmorphine and minopyrine N-demethylation were significantly greater in treated animals when compared to control values, while the microsomal hydroxylation of aniline was unaffected by clofibrate pretreatment. Clofibrate administrated elevated the microsomal cytochrome P-450 content. It is concluded that the extrapolation of drug-drug interactions with clofi-

ate in man based upon the selection of one or two
ugs may be misleading.

46 INFLUENCE OF FLUOROCARBON EMULSIONS ON HEPATIC METABOLISM IN PERFUSED RAT LIVER.

.) Goodman, M. N.; Parrilla, R.; Toews, C. J.
arvard Med. Sch., Boston, Mass.). *Am. J. Physiol.*
5(6):1384-1388, 1973.

e abilities of erythrocyte-free Krebs-Ringer-
carbonate buffer, erythrocyte-Krebs-Ringer-bicar-
nate buffer, and fluorocarbon-Krebs-Ringer-bicar-
nate buffer emulsions to maintain a viable per-
sed rat liver preparation were compared. At flow
tes of 30 ml/min, alanine gluconeogenesis, oxygen
nsumption, lactate and ketone body production, and
patic ATP concentrations were the same with all 3
ffer preparations. The cytosolic and mitochon-
ial redox states, as indicated by the hepatic
ctate:pyruvate and beta-hydroxybutyrate: aceto-
etate ratios, resp., were also the same with the
different buffers. However, at flow rates of 20
/min or less, the fluorocarbon-Krebs-Ringer-bicar-
nate and the erythrocyte-Krebs-Ringer-bicarbonate
ffers were superior to the erythrocyte-free buffer
e to their greater oxygen-carrying capacity. It
concluded that the fluorocarbon-Krebs-Ringer-bi-
rbonate and erythrocyte-Krebs-Ringer-bicarbonate
ffers are virtually identical in their ability to
intain a viable functioning perfused rat liver
eparation. No harmful effect was noted due to
e fluorocarbon emulsion on the tissue, however,
is not certain whether fluorocarbons interfere
th other vital events occurring in the liver.

47 LIVER REGENERATION AND URAEMIA. *(E.)*

Chen, T. S. N.; Leevy, C. M. (Coll. Med.
nt. New Jersey, Newark). *Br. J. Exp. Pathol.*
(6):591-596, 1973.

t experiments indicate that chemical antagonism to
A synthesis may account for the decrease in liver
ll replication and lymphocyte responsiveness en-
untered in liver disease and uremia. Investiga-
ons in male Sprague-Dawley rats of the incorpora-
on of [^{3}H]thymidine into DNA following CCl_4-induced
ver injury indicate that uremia decreases DNA syn-
esis in hepatocytes, mesenchymal cells, and lympho-
tes. Uremia had no effect on the severity of the
patic necrosis and CCl_4 (0.1/100g) did not signi-
cantly change the level of serum urea in nephrec-
mized animals. Dialysis or heating of uremic plas-
at 56° for 30 minutes abolished its suppressant
fect on hepatic DNA synthetic capacity. These ob-
rvations indicate that chemical inhibition of DNA
nthesis in uremia is responsible for alterations
hepatocytes and lymphocyte replication. Both
decrease in immunocompetence and reduced liver
generation in uremia may result from this chemical
fect. The specific factor or factors in uremic
asma responsible for reduced DNA synthesis remain
identified. However, preliminary data indicate
at the factors are dialysable and thermolabile.
is considered unlikely that urea, creatinine, or
anidosuccinic acid could account for the depression
of cellular DNA synthesis in renal failure since the first two have no effect on test results and the latter is stable at 56°.

1748 SUBMICROSOMAL DISTRIBUTION OF HEPATIC DRUG-METABOLIZING COMPONENTS IN THE GUNN RAT.

(E.) Guarino, A. M.; Reagan, R. L.; Gram, T. E. (Natl. Cancer Inst., Bethesda, Md.). *Pharmacology* . 10(5):257-271, 1973.

The submicrosomal distribution of a number of enzymes involved in the metabolism of xenobiotics was studied in livers of Wistar and Gunn rats. Compared with Wistar controls, ethylmorphine demethylase activity and cytochrome P-450 levels in smooth microsomes of homozygous Gunn rats were significantly decreased (about 20%). Both heterozygous and homozygous Gunn rats exhibited significantly elevated (20-60%) NADPH cytochrome c reductase activities in both smooth and rough microsomal fractions. UDP-glucuronyltransferase activity measured with phenolphthalein as substrate was barely detectable (< 10% of Wistar control) in smooth or rough microsomes of homozygous Gunn rats, but was only slightly reduced in the heterozygous animals. It is concluded that this report has offered evidence that in addition to decreased UDPGT activity there is also a slight impairment of nonglucuronidating drug-metabolizing pathway such as N-dealkylation in the Gunn rat. The dominant ethylmorphine demethylase activity was found in the smooth microsomal fractions of all three strains of rats, and the decreased ethylmorphine demethylase activity in the homozygous Gunn rats (20%) correlated well with the decreased levels (18%) of cytochrome P-450 levels. Such lowered drug-metabolizing capacity toward this substrate is associated with decreases in levels of cytochrome P-450.

1749 METABOLIC CHANGES INDUCED BY ETHANOL IN MUSCLE AND LIVER TISSUE OF THE RAT IN VIVO.

(E.) Fellenius, E.; Bjorkroth, U.; Kiessling, K. H. (Inst. Zoophysiol., Univ. Uppsala, Sweden). *Acta Chem. Scand.* 27(7):2361-2366, 1973.

The metabolic changes in the liver and skeletal muscle of female Wistar rats after infusion of ethanol into the rat *in vivo* were studied. Samples of the liver and muscle tissue were taken simultaneously by the freeze-clamp technique and analyzed for content of lactate, pyruvate, α-glycerophosphate, dihydroxyacetonephosphate, malate, adenine nucleotides, inorganic phosphate, creatinephosphate and creatine. The changes in the redox-state in the cytoplasm and mitochondria of the liver were measured as the [lactate]/[pyruvate]-ratio, and the [β-hydroxybutyrate]/[acetoacetate]-ratio, respectively. The ratios in the liver varied with the total amount of ethanol infused. The [lactate]/[pyruvate]-ratio of the muscle was not affected by the oxidation of ethanol. Thus the reduced state of the liver caused by the oxidation of ethanol and which partly can be exported to extrahepatic tissues will be re-adjusted in the resting muscle cell. The [β-hydroxybutyrate]/[acetoacetate]-ratio of the liver was, however, not restored to its normal value in the muscle. This was probably due to a low activity of the β-hydroxybutyrate dehydrogenase in the muscle. The changes of the adenine nucleotides were mainly in the level of AMP. These changes occurred both in the liver and in the muscle tissue and were related to the metabolism of acetate, the main product during oxidation of ethanol in the liver.

1750 RATE-LIMITING FACTORS IN ETHANOL OXIDATION BY ISOLATED RAT-LIVER PARENCHYMAL CELLS. EFFECT OF ETHANOL CONCENTRATION, FRUCTOSE, PYRUVATE AND PYRAZOLE.

(E.) Grunnet, N.; Quistorff, B.; Thieden, H. I. D. (Dept. Biochem., Univ. Copenhagen, Denmark). *Eur. J. Biochem.* 40(1):275-282, 1973.

Isolated rat-liver parenchymal cells from female Wistar rats oxidized ethanol at a rate of 1.4, 1.7, 1.9, and 2.5 μmol/min/ml packed cells at 4, 20, 40, and 65 mM ethanol, resp. Between 40 and 65 nM ethanol an abrupt 30% increase in the ethanol oxidation rate was noted. The activity of the NAD-dependent alcohol dehydrogenase in a homogenate of isolated cells corresponded to 1.25-5U/ml packed cells, depending on the assay method used. Fructose or pyruvate enhanced oxidation rate of ethanol by 1.4-2.0 μmol/min/ml packed cells independent of the ethanol concentration applied. No additive effect of the 2 compounds was observed. Pyrazole inhibited NAD dependent alcohol dehydrogenase activity in a homogenate of isolated cells as well as the unstimulated and the fructose-stimulated ethanol oxidation with a K_i-value of 9-13 μM. Pyrazole concentrations which inhibited the unstimulated ethanol oxidation only 30% inhibited the "frustose effect" 100%, indicating that the "fructose effect" is mediated via alcohol dehydrogenase. Pyrazole (4mM) only slightly inhibited that part of the ethanol oxidation not catalyzed by alcohol dehydrogenase, whereas pyrazole (18 mM) inhibited this pathway significantly. Pyrazole (50 M) had no effect on the basal ethanol oxidation rate, whereas the fructose-stimulated ethanol oxidation was 30% inhibited. At low concentrations of ethanol and in the absence of fructose, the rate-limiting step in ethanol oxidation appears to be dissociation of the enzyme-NADH complex. Fructose (or pyruvate) metabolism indirectly activates this dissociation by an increased rate of NADH oxidation, probably mediated via the "malic enzyme shuttle". Thus, in the presence of fructose or pyruvate, the maximal activity of ethanol dehydrogenase may be rate-limiting for the oxidation of ethanol. These results suggest that enzyme systems other than alcohol dehydrogenase participate in ethanol oxidation at high ethanol concentrations.

1751 BILIARY TRANSPORT OF SODIUM CHLORIDE: DEMONSTRATION OF THE EXISTENCE OF ACTIVE SODIUM TRANSPORT BY PERFUSED RAT LIVER.

(Fr.) Vanlerenberghe J.; Trupin, N.; Capon, C.; Nguyen, M. (Fac. Med., Univ. Lille, France). *Arch. Int. Physiol. Biochim.* 81(3):469-475, 1973.

To establish the action mechanism involved in the secretion of sodium in the bile, a study was made of bile secretion when rat liver was perfused with high concentrations of NaCl (20 mEq/liter) in the absence and presence of ouabain (1 x 10^{-4}M). The decrease in bile secretion which occurred immediately after addition of NaCl to the perfusion fluid was about the same in the presence and absence of ouabain (14% and 17%, resp.). This decrease lasted only 15 min, after which bile secretion normalized and then rapidly and progressively decreased again. The mean volume of bile secreted was significantly lower in the presence of ouabain than in its absence. Although the time required to reach equilibrium was about the same, the difference between the sodium concentration of perfusion fluid and that of bile was significantly greater in the presence of ouabain. Simultaneous addition of NaCl and ouabain to the perfusion fluid had no effect either on the difference between chloride concentrations in the perfusion fluid and bile or on the time required to reach equilibrium. The decrease which occurred in the volume of bile secreted, the concentration of sodium in the bile, and the sodium output can be accounted for by inhibition of (Na^+, K^+)ATPase by ouabain. These results support the hypothesis that sodium is actively transported from the blood to the bile.

1752 EFFECTS OF ESTROGEN UPON BILE: IMPLICATIONS WITH RESPECT TO GALLSTONE FORMATION.

(E.) Lynn, J.; Williams, L.; O'Brien, J.; Wittenberg, J.; Egdahl, R. H. (Boston Univ. Med. Ctr., Mass.). *Ann. Surg.* 178(4):514-524, 1973.

The effects of estrogens on hepatic bile flow and composition in awake female Rhesus monkeys with minimal interruption of the entero-hepatic circulation was investigated. The gallbladder was excluded from the system by double ligation of the cystic duct. Estriol (2, 4, or 8 mg/kg, i.v.) was administered in single dose. The 8 mg dose caused the greatest reduction in bile flow over 12 hr, the mean control level of 93.7 ml fell to 30.3 ml. Similarly the 8 mg dosage caused the greatest reduction in bile salt secretion, from 2.70 millimoles to 0.68 millimoles. Under control conditions a linear relation was observed between bile flow and bile salt secretion. The relation remained linear throughout the dose range. The intercepts of the plot of the hourly bile volume against bile salt secretion cut the verticle axis at a positive value, indicating that some proportion of bile salt is independent of bile flow. At all doses the 12 hr secretion rate of cholesterol and phospholipids was reduced, but not significantly. The only dose resulting in a significant reduction of the 12 hr phospholipid secretion was the 8 mg dose. There were dramatic changes in the relative composition of the bile at all dose levels. Estriol did not change the osmotic effect of a micromole of bile salt. Therefore, the fluid presented to the ductal system had a normal osmolarity even though bile salt secretion had been altered by estriol. From the viewpoint of gallstone formation, the most significant effects of estrogens are reflected by changes in the relative composition of bile. The induction of lithogenic bile occurred primarily through a reduced secretion of bile salts

ich was proportionately greater than the reduction
cholesterol and phospholipid secretion. Such
thogenic bile, when exposed to the well defined
liary tree stasis which occurs in pregnancy, may
sult in precipitation of microcrystals of choles-
rol, yielding to subsequent stone growth.

53 PARALLELISM BETWEEN MECHANICAL AND METABOLIC RESPONSES TO CHOLECYSTOKININ AND
STAGLANDIN E_2 IN EXTRAHEPATIC BILIARY TRACT.

) Andersson, K. E.; Andersson, R.; Hedner, P.;
sson, C. G. A. (Dept. Pharmacol., Univ. Lund,
den). *Acta Physiol. Scand.* 89(4):571-579, 1973.

mechanical effects of the prostaglandins E_1, E_2,
F_{2a} were investigated *in vitro* in isolated prep-
tions of guinea-pig gallbladder, cat gallbladder,
cat sphincter of Oddi. The actions of the pros-
landins, and particularly the effects of pros-
landin E_2, proved similar to those of cholecys-
inin, *i.e.* contraction of the gallbladder and re-
ation of the sphincter of Oddi were produced; the
ponses were not influenced by tetrodotoxin or by
ckade of adrenoceptors or cholinoceptors. In
anesthetized cat, prostaglandin E_2 increased
intraluminal gallbladder pressure and decreased
resistance to flow through the sphincter of
i. The contractile responses in guinea pig gall-
dder after prostaglandin E_2 were preceded by a
rease in the tissue levels of cyclic AMP and
activation of phosphodiesterase. The relaxation
duced by prostaglandin E_2 in the cat sphincter
Oddi was associated with an increase in the cyclic
content of the tissue, despite an increased
sphodiesterase activity. These metabolic changes
e similar to those observed in response to chole-
tokinin. These experiments showed that the
hanical effects of cholecystokinin on the extra-
atic biliary tract could be mimicked by the pros-
landins E_1, E_2, and F_{2a}, and of these most con-
tently by prostaglandins E_2. Similar to the ac-
ns of cholecystokinin, the prostaglandin induced
ponses were not influenced by pretreatment with
opine or by effective blockade of the adrenorecep-
functions in the gallbladder and in the sphinc-
of Oddi. These findings seem to exclude involve-
t of cholinoceptors and adrenoceptors in the me-
tion of the effects. The inability of tetrodotox-
to influence the effects of the prostaglandins
gests that these substances act directly on the
oth muscle cells without involvement of neuronal
ments.

54 EFFECTS OF ETHANOL ON MEMBRANE LIPIDS III. QUANTITATIVE CHANGES IN LIPID AND
TY ACID COMPOSITION OF NONPOLAR AND POLAR LIPIDS
MOUSE TOTAL LIVER, MITOCHONDRIA AND MICROSOMES
LOWING ETHANOL FEEDING.

(E.) Miceli, J. N.
w York Univ. Med. Ctr., N.Y.). *Lipids*
2):722-727, 1973.

effects of chronic ethanol consumption on the
els of various nonpolar and polar lipids and
nges in the composition of fatty acids associated
h these lipids were studied in the livers of male
ss-Webster mice. Mice (20) fed ethanol for 21
days had 12.7% more lipid in the total liver than controls, resulting from an increase in nonpolar lipids exceeding the loss in polar lipids. Mitochondria, however, had a loss of 23.4% total lipid attributable to losses in polar lipids. Microsomes had a loss of 25.1% lipid, resulting from losses of both nonpolar and polar lipids. The increase in the total liver of nonpolar lipids was primarily due to cholesterol esters which increased 300%. The loss of polar lipids can be attributed to choline phosphoglyceride and ethanolamine phosphoglyceride with losses in each case representing more than 5%. Mitochondrial and microsomal polar lipid losses also were due to choline and ethanolamine phosphoglycerides. Diphosphatidyl glycerol increased in all cases, even to a surprisingly high percentage in the total liver and microsomes. Triglyceride decreased in total liver and subcellular fractions, the greatest change occurring in the microsomes (15% total lipid). The amount of arachidonic (20:4) and docosahexaenoic acids (22:6) decreased in all lipids containing them in the total liver, mitochondria, and microsomes of the ethanol treated mice except in the choline phosphoglyceride of mitochondria where 20:4 increased. The large increase in cholesterol esters in the total liver and mitochondria is primarily oleic acid (18:1). Results of this study indicate that in both the mitochondria and microsomes of alcohol treated mice, a change has occurred in fatty acid distribution of the major lipids, which lends support to the hypothesis of enzyme hydrolysis. Also of significance were the increases in stearic acid content (18:0) of various lipids in the total liver and mitochondria of ethanol fed mice. It has been suggested that the decrease observed in liver mitochondria was due to decreases in the activity of the chain elongation-destruction system which converts linoleate to arachidonate. Since liver CoA content is decreased markedly by ethanol, a decrease in the activity of the enzyme system seems a logical explanation.

1755 POLYSACCHARIDES IN HUMAN GALLBLADDER WALL AND BILE.

(E.) Terho, T.; Laitio, M. (Dept. Physiol. Pathol. Anat., Univ. Turku, Finland). *Biochim. Biophys. Acta* 338(1):135-150, 1974.

Polysaccharides in human gallbladder wall and bile were isolated and characterized. In the gallbladder wall hyaluronic acid, heparan sulphate, dermatan sulphate and chondroitin 4- and/or 6-sulphate were found. Most hyaluronic acid and chondroitin 4- and/or 6-sulphate proteoglycan were extractable with 0.9% NaCl from the gallbladder wall, whereas dermatan sulphate proteoglycan was almost insoluble in 0.9% NaCl. In bile, hyaluronic acid and chondroitin 4- and/or 6-sulphate were found only in trace amounts. Two large molecular polysaccharides were isolated from the gallbladder wall and from bile. They were assumed to be the polysaccharide parts of so-called mucins. The polysaccharides were composed of glucosamine, galactosamine and galactose in the ratio of 3:1:4 or 9:1:10 and of different amounts of fucose, sialic acid and sulphate. The polysaccharides were fractionated further according to their sialic acid and sulphate content. In addition to these, large amounts of small molecular polysaccharides were isolated from the gallbladder wall and bile.

These polysaccharides consisted of varying amounts of glucosamine, galactose, glucose, mannose, fucose and sialic acids. In the gallbladder wall these polysaccharides (at the glycoprotein stage) were both soluble and insoluble in 0.9% NaCl. The "insoluble" polysaccharides were assumed to originate from structural or membrane-bound glycoproteins, e.g. plasma membrane glycoproteins.

1756 THE EFFECT OF HIGH-CARBOHYDRATE DIETS ON LIVER TRIGLYCERIDE FORMATION IN THE RAT.

(E.) Waddell, M.; Fallon, H. J. (Univ. North Carolina Sch. Med., Chapel Hill). *J. Clin. Invest.* 52(11):2725-2731, 1973.

Diets containing 75% glucose or fructose were fed to male Sprague-Dawley rats and the effect on liver triglyceride formation was studied both *in vivo* and *in vitro*. The results were compared with control rats fed laboratory chow. Both diets increased the capacity for triglyceride formation from sn-glycerol-3-P by rat liver homogenates and correspondingly increased incorporation of [1,3-^{14}C] glycerol into hepatic triglyceride by the intact animal. These independent measures of hepatic triglyceride production changed with a similar time-course characteristic for each diet. The 75% fructose diet produced a greater increase (5-10-fold) in both determinations, and reached a maximum after 11 days. Despite the increase in hepatic triglyceride formation by both diets, only the fructose diet caused consistent and sustained increase in serum triglyceride. This results probably from differences in the fractional rate of serum triglyceride removal between the 2 groups. When Triton WR-1339 inhibited serum triglyceride removal, both diets increased incorporation of [1,3-^{14}C] glycerol in serum triglyceride *in vivo* and increased serum triglyceride level above that in control rats.

1757 UREA SYNTHESIS IN LIVER SECTIONS FROM UREMIC RATS.

(Ger.) Zimmermann, E.; Selzer, H.; Hohenegger, H. (Whilhelminespital, Vienna, Austria). *Wien. Med. Wochenschr.* 123(23):365-367, 1973.

Of 22 unilaterally nephrectomized male Wistar rats, 11 underwent a second nephrectomy 3 weeks later. The rats were bled 45 hr after removal of the second kidney, their livers were removed, and liver slices were incubated in a Warburg apparatus at 37 C for 65 min with a solution containing 105 mEq/liter Na^+, 2 mEq/liter K^+, 2 mEq/liter Ca^{++}, 82 mEq/liter Cl^-, 27 mEq/liter HCO_3^-, 100 mg/100 ml glucose and 40 mg/100 ml NH_4Cl. Urea (406 mg/100 ml), creatine (6.23 mg/100 ml), and potassium (9.33 mEq/liter) concentrations and the pH (7.15) were significantly increased in the blood of uremic rats. Values for blood sodium concentrations, liver dry weight, and liver tissue water did not differ significantly between uremic rats and unilaterally nephrectomized controls. The increase in urea occurring in liver slices during incubation in the Warburg apparatus was of the same order of magnitude for both groups of animals. It is concluded that increased blood nitrogen levels did not inhibit urea synthesis in the livers of uremic rats. The large increase which occurs in blood urea levels after hemodialysis cannot be accounted for by changes in urea synthesis in the liver.

1758 ROLE OF UREA IN THE HYPERAMMONEMIA OF GERM-FREE ECK FISTULA DOGS.

(E.) Nance, F. C.; Kaufman, H. J.; Kline, D. G. (Louisiana State Univ. Sch. of Med., New Orleans, La.). *Gastroenterology* 66(1):108-112, 1974.

Hyperammonemia and symptomatic hepatic encephalopathy occur in germ-free (GF) animals after creation of an Eck fistula. The role of urea as a possible substrate for ammonia production in germ-free Eck fistula beagles was assessed in this experiment. End to side portacaval shunts were performed in GF and conventional dogs. After recovery, 40 g of urea in 200 ml of water were given by orogastric tube, and blood ammonia levels measured 3 and 6 hr postingestion, both in GF and conventional Eck fistula dogs. Conventional dogs had massive increases in blood ammonia averaging 483% after urea ingestion. GF dogs had only a minimal change averaging -6.35%. Hydrolysis of urea plays no role in the hyperammonemia of GF Eck fistula dogs, in striking contrast to conventional dogs and probably patients. The experiment provides indirect evidence that there are no endogenous ureases present in the gastrointestinal tract of the dog.

1759 INTESTINAL VERSUS HEPATIC CONTRIBUTION TO CIRCULATING TRIGLYCERIDE LEVELS.

(E.) Cenedella, R. J.; Crouthamel, W. G.; Mengoli, H. F. (West Virginia Univ. Med. Ctr., Morgantown). *Lipids* 9(1):35-42, 1974.

Using intravenous injected [2-^{3}H] glycerol, measurements were made of the kinetics of appearance and disappearance of circulating [^{3}H] labeled triglyceride in male Sprague-Dawley rats fed a fat free diet containing either no orotic acid (controls) or 2% orotic acid. Following injection of [^{3}H] glycerol, more time is required for the initial appearance of [^{3}H] triglyceride in the circulation of orotic acid treated rats than controls. The sustained entry of triglyceride into the circulation of orotic acid fed rats was only one-half times as rapid as that seen for control rats. About 10% as much [^{3}H] triglyceride entered the circulation of the orotic acid treated rats as compared with controls. However, the clearance of [^{3}H] triglyceride from the circulation of the orotic acid fed rat was only about one-half times as rapid as that of the control rat. This apparently is due to differences between the lipoproteins produced by the intestines and liver, rather than to changes in the ability of the orotic acid fed animal to clear lipoprotein-triglyceride from the circulation. Labeled lipoproteins taken from controls and injected into orotic acid treated rats were cleared from the circulation more than twice as rapidly as those taken from orotic acid fed rats and injected into controls. Considering the measured levels of plasma triglyceride synthesis and the slower turnover of the triglycerides produced by the orotic acid fed rat, the findings dicate that the intestines supply 20% or more of e total plasma triglyceride in the absence of etary fat.

60 TOWARD AN ARTIFICIAL LIVER. II. REMOVAL OF CHOLEPHILIC ANIONS FROM DOGS WITH LIARY OBSTRUCTION, BY HEMOPERFUSION THROUGH ARGED AND UNCHARGED RESINS. *(E.)* Willson, R. A.; gmann, A. F.; Kuster, G. G. R. (Mayo Clin. Mayo n., Rochester, Minn.). *Gastroenterology* 66(1): -107, 1974.

dogs with biliary obstruction, hemoperfusion rough an anion exchange resin or an uncharged sin, resin was carried out to determine whether lected protein-bound anions, normally extracted by e liver and excreted in bile, could be removed. lfobromophthalein, chenodeoxycholic acid, and tal bilirubin were continuously removed by the sins during the 2-hr perfusion period. Indocyanine een was not removed. Blood levels of chenodeoxyolic acid and bilirubin in the dogs remained latively constant, but adsorption of anions to the lumn continued throughout the perfusion, suggesting bilization of tissue stores. Bile acids were adrbed to a greater extent by the uncharged resin an by the anion exchange resin in agreement with *vitro* equilibrium binding studies. Similarly, lfobromophthalein was removed more effectively the anion exchange resin during hemoperfusion d *in vitro* studies. Hemolysis was minimal. Elecolytes remained unchanged. Serum protein concenations remained constant, but the uncharged resin sorbed some prealbumin and caused some denaturaon of ceruloplasmin. Hemoperfusion through charged uncharged resins appears to be a feasible produre for removal of protein-bound anions in an imal model designed to simulate the excretory dect present in hepatic failure, and provides an perimental method for assessing the toxicity of otein-bound metabolites.

51 UPTAKE OF MATERIALS BY THE INTACT LIVER. THE EXCHANGE OF GLUCOSE ACROSS THE CELL MBRANES. *(E.)* Goresky, C.A.; Nadeau, B.E. cGill Univ. Med. Clin., Montreal, Canada). *J. n. Invest.* 53(2):634-646, 1974.

process of entry of D-glucose into and exit from ver cells was studied with the multiple indicadilution technique. Labeled red cells (a vaslar indicator), labeled sucrose (an extracellular ference), and labeled D-glucose were rapidly incted into the portal vein, and from serially mpled hepatic venous blood, normalized outflowne patterns were obtained. The labeled red cell rve rises to an early high peak, and decays rapidand that for sucrose reaches a later and lower k and decays less rapidly, but generates an ivalent area. The curve for labeled D-glucose gins with that for labeled sucrose, gradually es to a peak which is later and substantially ver than that for sucrose, and then decreases wly. At high glucose levels this curve assumes quared-off shape, rises fairly quickly to its hest level, at the time of the sucrose peak, and then slowly decreases. Phlorizin and galactose infusion result in the emergence of a pronounced early peak, under the sucrose peak; and the curve for tracer L-glucose approaches that for sucrose. Two components are resolved from the D-glucose curves, by model analysis: throughout material, which has not entered the cells; and exchanging material, which has entered and later returned to the circulation. The analysis provides estimates of the kinetic entrance and exit coefficients; and from these, saturation of both the entrance and exit processes was evident. The characteristic transport parameters were determined. For both entrance and exit, a common *Km*, 2,170 mg/100 ml, and transport maximum, 5.13 mg s^{-1} (ml intracellular fluid)$^{-1}$, were found. Both these values are exceedingly large. Phlorizin and galactose produced competitive inhibition; the transport process was found to be relatively stereospecific; and sudden infusion of hypertonic glucose produced countertransport of labeled D-glucose.

1762 INFLUENCE OF ALBUMIN ON THE EXTRAVASCULAR DISTRIBUTION OF UNCONJUGATED BILIRUBIN. *(E.)* Bloomer, J. R.; Berk, P. D.; Vergalla, J.; Berlin, N. I. (Natl. Cancer Inst., Bethesda, Md.). *Clin. Sci. Mol. Med.* 45(4):517-526, 1973.

The influence of albumin on the extravascular distribution of unconjugated bilirubin was studied. [^{3}H]Bilirubin and ^{131}I-labelled albumin were given simultaneously to 6 healthy adults by intravenous route and the amounts in the plasma were measured for several days. Multicompartmental analysis of the data showed that the rate of movement of [^{3}H]bilirubin from the plasma into the extrahepatic extravascular space was 29.7± 7.3% of the plasma pool/hr, whereas as the rate of movement of ^{131}I-labelled albumin from plasma into the extravascular space was only 7.2 ± 1.0% of the plasma pool/hr. [^{14}C]Bilirubin was found to equilibrate throughout the body of a child with the Crigler-Najjar syndrome within 24 hr of intravenous administration, whereas ^{131}I-labelled albumin required 4-5 days in human subjects. Multicompartmental analysis of the plasma data in the 6 healthy adults indicated that the mass of material in the extrahepatic extravascular space relative to that in plasma was greater for unconjugated bilirubin than for albumin. Studies of the tissue distribution of unconjugated bilirubin in homozygous Gunn rats demonstrated that the organs which comprise the rapidly exchanging extravascular albumin pool (liver, kidney and intestine) accumulated unconjugated bilirubin in excess of their albumin content, whereas less amounts of unconjugated bilirubin were accumulated in the tissues which make up the slowly exchanging extravascular albumin pool (muscle, fat and skin). These findings indicate that unconjugated bilirubin moves more rapidly between plasma and extrahepatic extravaxcular sites than can be accounted for by transport bound to albumin. They also indicate that extravascular binding of unconjugated bilirubin includes tissue sites, as well as extravascular albumi

1763 THE RAPID CHANGES OF HEPATIC GLYCOLYTIC ENZYMES AND FRUCTOSE-1,6-DIPHOSPHATASE AC-

TIVITIES AFTER INTRAVENOUS GLUCAGON IN HUMANS.

(E.) Greene, H. L.; Taunton, O. D.; Stifel, F. B.; Herman, R. H. (Fitzsimons Army Med. Ctr., Denver, Colo.). *J. Clin. Invest.* 53(1):44-51, 1974.

Glucagon (0.04-0.09 mg/kg/min) was given intravenously for either 2 or 3 min to 8 patients with fasting-induced hypoglycemia. Liver biopsy specimens were obtained before and immediately after the glucogan infusion. The glucagon caused a significant increase in the activity of FDPase (from 50 to 72 nmol/mg protein/min) and a significant decrease in the activities of phosphofructkinase (PFK) (from 92 to 41 nmol/mg protein/min) and pyruvate kinase (PK) (from 309 to 165 nmol/mg protein/min). The glucagon infusion also caused a significant increase in hepatic cyclic AMP concentrations (from 41 to 233 nmol/mg protein). Two patients with debrancher enzyme deficiency who had biopsy specimens taken 5 min after the glucagon infusion had persistence of enzyme deficiency and cyclic AMP changes for at least 5 min. One child with glucose-6-phosphatase deficiency was given intravenous glucose (150 mg/kg/min) for a period of 5 min after the glucagon infusion and biopsy. The plasma insulin concentration increase from 8 to 152 μU/ml and blood glucose increased from 72 to 204 mg/100 ml. A third liver biopsy specimen was obtained immediately after the glucose infusion and showed that the glucagon-induced effects on PFK and FDPase were completely reversed. The glucagon infusion caused an increase in hepatic cyclic AMP concentration from 38 to 431 nmol/mg protein but the glucose infusion caused only a slight decrease in hepatic cyclic AMP concentration (431 to 384 nmol/mg protein), which did not appear to be sufficient to account for the changes in enzyme activities. Hepatic glucose-6-phosphatase and fructose-1, 6-diphosphate aldolase activities were not altered by either the glucagon or the glucose infusion in any patients. Cyclic AMP (0.05 mmol/kg) was injected into the portal vein of adult rats and caused enzyme changes similar to those seen with glucagon administration in humans. These findings suggest that rapid changes in the activities of PFK, PK, and FDPase are important in the regulation of hepatic glycolysis and gluconeogenesis, respectively, in humans and that cyclic AMP may mediate the glucagon- but probably not the glucose-insulin-induced changes in enzyme activities.

1764 RELATIVE SECRETION OF CHOLESTEROL-4-^{14}C IN THE BILE AND UPPER AND LOWER SMALL INTESTINE WASHINGS OF THE BILE FISTULA RABBIT. *(E.)*

Buchwald, H.; Gebhard, R. L.; Varco, R. L. (Univ. Minnesota Med. Sch., Minneapolis). *Surgery* 75(2): 266-273, 1974.

The secretion of circulating labeled cholesterol by a total biliary fistula, by the isolated upper half of the small intestine, and by the isolated lower half of the small intestine was measured in 21 anesthetized rabbits over an average time of 13 hr. From the secreted radioactivity, ratios were calculated and the 3 key average radioactivity excretion ratios were: bile counts per min (cpm)/combined total number of counts per min (bile counts per min + upper small intestinal counts per min + lower small intestinal counts per min 0.5470, bile counts per min/tot number of small intestinal counts per min, 1.4948; a jejunal-ileal counts per min/distal ileal counts per min, 1.6031. The measured average jejunal-ileal/dis ileal length ration was 1.338. It is concluded that the rabbit under the acute conditions of this experiment: (1) the cholesterol that is secreted in the bile is 1 1/2 times the amount secreted by the small intestinal mucosa. (2) Small bowel mucosal choleste ol secretion, on the basis of comparison of the jejunal-ileal/distal ileal counts per min and length ratios, does not appear to be localized to either th upper or the lower half of the small intestine. (3) Bowel mucosal cholesterol secretion is independent of the presence of bile salts in the intestinal lumen.

1765 PRODUCTION OF SERUM PROTEINS BY PRIMARY CULTURES OF ADULT HUMAN LIVER. *(E.)*

LeGuilly, Y.; Launois, B.; Lenoir, P.; Bourel, M. (Pontchaillou Hosp., Rennes, France). *Biomedicine* 19:248-255, 1973.

Plasma protein synthesis of adult human liver cells was studied by radioimmunoelectrophoresis of the culture medium. All determinations were made on the basis of primary cultures from explants of human adult tissue: 15 cultures of liver and 1 of aponeurosis. Eleven antihuman goat or horse antisera were used: 1 multivalent antiserum, and 10 specific antisera each precipitating one of the following human proteins: orosomucoid, α_1 antitripsin, ceruloplasmin, fibrinogen, transferrin, haemopexin, albumin, β lipoprotein, α_2 macroglobulin and haptoglobin The 10 plasma proteins tested were found in all of the 15 liver primary cultures but were never present simultaneously in the medium of a single primary culture. The evidence suggests that orosomucoid, α_1 antitrypsin, ceruloplasmin and fibrinogen are produced by epithelial cells, transferrin and hemopexin by epithelial-like cells and albumin, β lipoprotein, α_2 macroglobulin and haptoglobin by both types of cells.

1766 RELATIONSHIP OF ETHANOL TO CHOLINE METABOLISM IN THE LIVER: A REVIEW. *(E.)*

Barak, A. J.; Tuma, D. J.; Sorrell, M. F. (Univ. Nebraska Med. Ctr., Omaha). *Am. J. Clin. Nutr.* 26(11):1234-1241, 1973.

Despite the fact that ethanol ingestion and choline deficiency appear to have related effects on the liver, a true relation of ethanol metabolism to choline metabolism in this organ has not been shown. A technique for the quantitative measurement of choline uptake by the isolated perfused liver has been developed and has served as a convenient model for studies involving hepatic ethanol-choline relations. These studies have shown that a specific choline oxidase antagonist, 2-amino-2-methyl-1-propanol, and 2 nonspecific choline oxidase inhibitors depressed hepatic choline uptake. This indicates that the uptake is primarily a function of the choline oxidative pathway. Circulation of ethanol in liver perfusates or chronically feeding ethanol to rats

nhanced choline uptake. Pyrazole inhibition of
his ethanol-induced increase suggests that ethanol
ust be metabolized to produce its effect. Inves-
igation of the effects of 2 metabolic products of
thanol, acetate and NADH, demonstrated that in-
reased NADH generation due to hepatic ethanol me-
abolism may cause the observed increase in choline
tilization. The ability of the choline oxidase
nhibitor to block the effect of ethanol suggests
hat the increased choline requirement due to alco-
ol may result from ethanol metabolism stimulating
he oxidative degradation of choline in the liver.
hese results suggest a direct metabolic relation
etween ethanol administration and choline metabol-
sm, which may have an effect on lipid transport or
he pathogenesis of the alcoholic fatty liver.

767 DEHYDROCHOLATE METABOLISM AND THE EFFECT
OF DEHYDROCHOLATE ON BILIARY SECRETION IN
HE DOG. *(Fr.)* Desjeux, J. F.; Erlinger, S.; Du-
ont, M. (Beaujon Hosp., Clichy, France). *Biol.*
astroenterol. (Paris) 6(1):9-18, 1973.

quimolar solutions of sodium taurocholate or sodium
ehydrocholate (22.5-75 μM/ml) were infused i.v. in-
o 8 anesthetized dogs and 1 unanesthetized dog
ith a Thomas duodenal cannula. Rates of infusion
anged from 22.5-75 μM/min for 50-105 min. Total
ile salts were determined with 3α-hydroxysteroid
ehydrogenase, and bile acids were separated by
hin-layer chromatography. Bile was fractionated
ultracentrifugation in a cesium chloride solution.
ile output averaged 40% higher during dehydrocho-
ate than during taurocholate infusion. A signi-
icant correlation was found between the amount of
ehydrocholate infused and the excretion of bile
alts hydroxylated in the 3α position. About 50%
the dehydrocholate administered was converted in-
3α-hydroxylated derivatives in the bile. No un-
hanged dehydrocholate was isolated from the bile
uring dehydrocholate infusion; 2 unidentified meta-
olites were isolated by thin-layer chromatography.
liary excretion of both phospholipids and choles-
erol were significantly lower with dehydrocholate
han with taurocholate infusion. The results of
tracentrifugation of bile secreted during dehydro-
olate infusion are compatible with the presence
a macromolecular complex containing dehydrocholate
tabolites and bile pigments but not phospholipids
cholesterol. In the dog it is concluded that
hydroxylated metabolites excreted into the bile
ring dehydrocholate infusion are apparently able
form macromolecular aggregates or micelles but
not enhance phospholipid and cholesterol excre-
on. The increase in bile output caused by dehydro-
olate infusion may result from the specific action
dehydrocholate metabolites on electrolyte and wa-
r secretion by the hepatocytes rather than from
e appearance of dehydrocholate in the bile.

68 FATTY LIVER AND CIRRHOSIS IN LIPOTROPE-
DEFICIENT MALE RATS. *(E.)* Rogers, A. E.;
wberne, P. M.; (Dept. Nutr., Massachusetts Inst.
ch., Cambridge). *Am. J. Pathol.* 73(3):817-820,
73.

Rats (Charles River CD strain, Wistar, and Fischer) were fed from weaning a diet deficient in choline, methionine, vitamin B_{12} and folic acid, high in fat and adequate in amino acid content other than methionine. Such a diet induced defective lipid and drug metabolism, fatty liver of increasing severity, depression of serum lipids and increased hepatocyte turnover over a 6-month period followed by fibrosis and cirrhosis at 6-12 months. The severity of deficiency and rapidity with which fatty liver and cirrhosis develop are governed by dietary levels of the nutrients listed above and by the rat's age. Marginal lipotrope deficiency may also be produced which induces fatty liver but not cirrhosis and is useful in long-term studies of chemical toxicity and carcinogenicity for it supports nearly normal growth and longevity while inducing the biochemical abnormalities found in severe deficiency. The fatty liver and cirrhosis induced in rats closely resemble the human disease in gross and microscopic lesions and development of hepatic dysfunction. There is an exception in the case of alcoholic hepatitis and its associated hyaline cytoplasmic deposits which may require exposure to alcohol or other hepatotoxins. The sensitivity of cirrhotic patients to environmental carcinogens as suggested by their high incidence of esophageal and hepatic cancer is being investigated. Aflatoxin B1 and diethylnitrosamine are more effective hepatic carcinogens in lipotrope-deficient rats than in normal rats, an effect which may be mediated through impairment of drug metabolism in the endoplasmic reticulum.

1769 STUDY ON THE MECHANISM OF INDUCTION OF ALKALINE PHOSPHATASE ACTIVITY IN RAT LIVER AFTER BILE FLOW OBSTRUCTION. *(E.)* Ferwerda, W.; Stepan, J. (Dept. Chem. Physiol., Vrije Univ., Amsterdam, Netherlands). *Hoppe Seylers Z. Physiol. Chem.* 354(10/11):1462-1472, 1973.

The inducible liver alkaline phosphatase from adult male Wistar rats with extrahepatic cholestasis and from controls was purified by butanol extraction, Sephadex G-200 filtration, Sepharose 6B filtration in the presence of an ionic detergent, and, as the final step, preparative polyacrylamide gel electrophoresis. The enzyme from cholestatic rats was purified more than 1000-fold. The specific enzyme activity increased from 3.2 to 3296 units/mg. For sham-operated rats the purification was nearly the same, the specific enzymic activity increasing from 1.0 to 1146 units/mg. The preparations were of a high degree of purity as shown by analytical polyacrylamide gel electrophoresis. A double band of activity was found in the case of cholestasis, but a single one was obtained after sham-operation. No significant alteration of incorporation of ^{14}C-labelled amino acids and $[^{14}C]$glucoseamine into the purified inducible alkaline phosphatase of cholestatic rats was found. During the first hours after obstruction, the incorporation of ^{14}C-labelled amino acids into total liver protein was about 20% less in cholestatic rat liver than in the livers of sham-operated rats. The finding that alkaline phosphatase in the cholestatic rat liver is 3 times more active than in the control liver indicates that a more active enzyme molecule is formed during cholestasis. No evidence was uncovered to suggest that either an increased rate of alkaline phosphatase synthesis or a decreased rate of catabolism of the enzyme occurred after cholestasis.

1770 THE CHOLERETIC EFFECTS IN DOGS OF THE SYNTHETIC C-TERMINAL OCTAPEPTIDE OF CHOLECYSTOKININ AND OF TWO PEPTIDE MIXTURES, G1 AND G2, DERIVED FROM UPPER HOG INTESTINE. *(E.)* Thulin, L. (Karolinska Inst., Stockholm, Sweden). *Acta Chir. Scand.* 139(7):641-644, 1973.

The hepatic bile flow was studied in 5 dogs with permanent external common duct fistulas during i.v. infusions of synthetic octapeptide of cholecystokinin and 2 polypeptide mixtures, denoted G1 and G2, extracted from upper hog intestinal mucosa as late side fractions during the preparation of secretin. Infusions of 90-120 min were given to animals which had fasted for 16-22 hr. Pre-infusion bile flow values were used as controls. Synthetic C-terminal octapeptide of cholecystokinin (1-80 Ivy dog units/kg/hr) was administered in 19 experiments in 3 dogs. The bile flow increased to an average of 200% of control at 5 units/kg/hr. No further response was obtained with higher doses. Polypeptide mixture G1 (5-100 μg/kg/hr) was administered in 11 experiments in 3 dogs. The bile flow increased to 350-400% of control at doses of 50-100 μg/kg/hr. Maximum response was probably not obtained. Polypeptide mixture G2 (5-100 μg/kg/hr) was administered in 15 experiments in 4 dogs. The bile flow increased to about 275% of control at doses of 40-50 μg/kg/hr with no further increase at higher dosages. The results indicate that the choleretic activity of cholecystokinin is similar to that of the natural hormone and that G1 and G2 must be included in the group of polypeptides having choleretic activity.

1771 PROTECTIVE INFLUENCE OF DIPHENYL-p-PHENYLENEDIAMINE ON HYDRAZINE INDUCED LIPID PEROXIDATION AND HEPATIC INJURY. *(E.)* Di Luzio, N. R.; Stege, T. E.; Hoffman, E. O. (Tulane Univ. Sch. Med., New Orleans, La.). *Exp. Mol. Pathol.* 19(3):284-292, 1973.

The influence of diphenyl-p-phenylenediamine on hydrazine-induced hepatic toxicity was assessed so that its ability to modify chemically induced hepatic injury might be evaluated. The administration of hydrazine (4 mg/100 g) to female Sprague-Dawley rats caused a 7-fold increase in liver triglyceride concentration. A 60% inhibition of triglyceride accumulation occurred in the diphenyl-p-phenylenediamine-treated group. Hydrazine also increased hepatic lipid peroxidation as reflected by malonaldehyde formation. The increase in malonaldehyde formation was prevented by diphenyl-p-phenylenediamine treatment. In contrast to profound hepatic necrosis observed following hydrazine, livers from diphenyl-p-phenylenediamine treated rats which received hydrazine showed only mild architectural alterations. The hypoglycemia and retention of BSP which developed upon hydrazine administration were not modified by diphenyl-p-phenylenediamine. The ability of the lipid soluble antioxidant, diphenyl-p-phenylenediamine, to significantly inhibit hydrazine-induced fatt infiltration, necrosis, and lipid peroxidation further accents the potential of employment of appropriate antioxidants in the prevention of chemically-induced hepatic injury.

1772 SOLUBILIZATION AND CHARACTERIZATION OF HEPATIC BILIRUBIN UDP-GLUCURONYLTRANSFERASE *(E.)* Gregory, II, D. H.; Strickland, R. D. (Albuquerque VA Hosp., N.M.). *Biochim. Biophys. Acta* 327:36-45, 1973.

The hepatic enzyme, bilirubin UDPglucuronyltransferase has been solubilized in stable form by treating rat liver microsomes with 10% (by weight) dissolved digitonin at pH 7.8. All enzyme activity was associated with the rough membranes of the endoplasmic reticulum as shown by ultracentrifugation of selected density gradients in combination with electron microscopy. Proof of solubilization was determined by analytic ultracentrifugation, gel filtration, and electron microscopy which indicated that the enzyme was an homogeneous protein with a calculated molecular weight in the range of 150,000. From the homogeneous Schlieren pattern obtained by analytical ultracentrifugation, the sedimentation coefficient of the major component was estimated to be 6.9 S. The assay characteristics of soluble transferase differ in several ways from those observed in homogenates. The pH optimum for soluble enzyme was 7.8. Magnesium ion, essential for enzyme activity, could vary in concentration from 5-20 mM without affecting results. Exposure to temperatures in excess of 45°C for 3 min reduced enzyme activity by 80%. Solubilized preparations were stable for at least 7 days when stored at 4 C. Now that a stable and soluble preparation of hepatic glucuronyl transferase is available, studies concerning substrate specificity can proceed.

1773 INFLUENCE OF HYDROCORTISONE ON BILE FORMATION IN THE RAT. *(E.)* Dumont, M.; Erlinger, S. (Beaujon Hosp., Clichy, France). *Biol. Gastroenterol. (Paris)* 6(3):197-203, 1973.

The effect of hydrocortisone on bile flow, bile acid excretion, erythritol and sucrose clearance, and sodium excretion into bile has been studied. The influence and possible mode of action of this hormone on bile formation in the male Sprague-Dawley rat was thus investigated. Several observations were apparent during hydrocortisone infusions. The flow of bile increased. This effect was dose-dependent, a maximal increase of approximately 75 p. 100 for a dose of 2 mg/min/100 g. Bile acid excretion was not modified. Erythritol clearance increased in parallel to bile flow, suggesting that the increased flow was of canalicular (hepatocytic) rather than ductal or ductular origin. Sucrose clearance was not significantly different during hydrocortisone choleresis and during a taurocholate induced choleresis of similar magnitude. This finding supports the view that hydrocortisone did not modify the permeability of the canalicular membrane to this solute, and, presumably, to water and ele-

rolytes. Sodium excretion increased. These obser-
ations suggest that hydrocortisone stimulates the
ile acid independent fraction of canalicular bile
low in the rat.

'74 USE OF HEPATIC CELL MEMBRANE POTENTIAL MEASUREMENT TO EVALUATE METHOD OF LIVER
RESERVATION. *(E.)* Lambotte, L. (Lab. Exp. Surg.,
niv. Louvain, Belgium). *Surgery* 74(4):509-518,
)73.

method of evaluating liver viability based on
easurement of hepatic cell membrane potential with
croelectrodes was used to assess the protection
ven by various drugs during liver anoxia at reduced
mperature. Isolated canine livers were perfused
th blood at 20 C for 2 hr, submitted to a circu-
tory arrest of 2 hr, and reperfused for 2 hr to
serve the fall of membrane potential produced by
oxia and its subsequent recovery. Pretreatment
th Tham (0.3 M), chlorpromazine (50 mg), and
thylprednisolone (125 mg) did not modify the course
the membrane potential during the second period
perfusion. In contrast, addition of isoproterenol
rkedly improved the recovery of the membrane poten-
al. A favorable effect of isoproterenol was also
served when the liver was rinsed with Ringer's
ctate solution and kept 3 hr at 5 C or kept anoxic
20 C 3 hr before the second perfusion. Isopro-
renol was also of some benefit when given after
2 hr circulatory arrest but not after a 4 hr cir-
latory arrest. Isoproterenol thus protects the
ver during anoxia and improves the recovery of a
derately damaged liver. This effect is related
a reduction of membrane permeability to sodium,
sulting in decreased accumulation of sodium in-
acellularly and decreased energy expenditure by
e sodium pump. Confirmation of these results was
tained in liver transplantation.

75 ACQUISITION OF AN EMBRYONAL BIOCHEMICAL FEATURE IN THE RAT LIVER AFTER PORTACAVAL
JNT. *(E.)* Colombo, J. P.; Bircher, J. (Hosp.
rne, Bern, Switzerland). *Experientia*
(10):1232-1233, 1973.

patic γ-glutamyl transpeptidase was measured in
ult male Sprague-Dawley rats 10, 20, and 30 days
ter an end-to-side portacaval shunt to determine
ether some of the hepatic consequences of a porta-
val shunt might be a regression of the hepatocytes
a more immature or embryonal state. It is known
at this enzyme is 10 to 20 times more active in
e newborn than in the adult rat. After 10 days
e glutamyl transpeptidase activity had increased
-fold and remained at this level throughout the
riod of observation. The high enzyme activity in
rtain rat hepatomas which contain glycogen, pro-
ce bile, and have a high level of glucose-6-
osphatase suggests that glutamyl transpeptidase
be activated in parenchymatous liver cells during
e carcinogenic process. The generally recognized
or morphological alterations occurring in the
ver of shunted rats are not sufficient to explain
s 10-fold increase in enzyme activity. Whether
s reversion to a biochemical feature predominant
in the fetus is limited to a few specific enzymes or represents a form of generalized hepatic immaturity after portacaval shunts is not certain at this point.

1776 BIOSYNTHESIS OF LIPIDS FROM U-^{14}C GLUCOSE BY THE ISOLATED LIVER PERFUSED IN HYPOXIA. *(E.)* Soler-Argilaga, C.; Infante, R.; Polonovski, J. (Fac. Med. Saint Antoine, Paris, France). *Biomedicine* 19(9):399-402, 1973.

The effects of hypoxia on glucose metabolism and the synthesis of liver lipids were investigated in male Wistar rats. Hypoxia caused a reduction in the hepatic glycogen level and a rise in glycemia during the perfusion, most significant in livers from fed rats perfused in hyperglycemia. Hypoxia did not significantly modify glucose utilization, but increased its production, particularly in the fed rat livers having higher glycogen levels. When perfused in hypoxia, the amount of circulating glucose transformed into lipid glycerol was slightly increased, but no significant difference in the incorporation of 14-C into the fatty acids was observed. These results show that hypoxia increased hepatic production of glucose without modifying its utilization and brought about a reduction of specific activity of glucose following the anaerobic glycolytic pathway. Consequently, the slight increase in incorporation of circulating glucose in glyceride and phosphoglyceride glycerol found after oxygen reduction is partly due to overproduction of lipid glycerol from glucose under these conditions. Overproduction of lipid glycerol is assumed to result from increased synthesis of L-α-glycerophosphate.

1777 STUDY OF ALBUMIN SYNTHESIS IN RELATION TO UREA SYNTHESIS. *(E.)* Oratz, M.; Schreiber, S. S.; Rothschild, M. A. (New York VA Hosp., N.Y.). *Gastroenterology* 65(4):647-650, 1973.

Albumin synthesis in the isolated perfused rabbit liver was simultaneously measured immunologically by the ^{14}C-carbon dioxide method. Since this ^{14}C method requires the assay of synthesized urea carbon-specific activity, urea synthesis was varied by dietary alterations and by perfusion with alcohol (200 mg/100 ml), tryptophan (10 mM), arginine (10 mM), and ornithine (10 mM). Albumin synthesis rates, determined by the 2 methods agreed well over a 10-fold range of albumin and urea synthesis rates. Perfusion with arginine or ornithine increased albumin synthesis 3-fold compared with fasted control values. These data suggest that, kinetically, arginine acts as a single precursor pool for albumin and urea synthesis, and support the validity of the ^{14}C-carbon dioxide method *in vitro*.

1778 DRUG HYDROXYLATION AND GLUCURONIDATION IN LIVER MICROSOMES OF PHENOBARBITAL-TREATED RATS. *(E.)* Vainio, H. (Dept. Physiol., Univ. Turku, Finland). *Xenobiotica* 3(11):715-725, 1973.

The environmental requirements of the UDP-glucuronyltransferase and the mixed function oxidase in hepatic

... microsomes were studied in 64 adult male Wistar rats. The rise in *p*-nitroanisole *O*-demethylase activity in liver microsomes after phenobarbital treatment of rats slightly preceded, and was greater than, the increase in hepatic microsomal UDP-glucuronyltransferase activity. Predigestion of hepatic microsomes with trypsin was necessary in order to detect the increase in UDP-glucuronyltransferase activity. Digitonin was not able to reveal the increase induced by phenobarbital. Trypsin digestion of hepatic microsomes solubilized about 30% of the proteins in control rats and 45% in microsomes isolated from phenobarbital treated rats. The amount of solubilized phospholipids was only about 6% in both cases. The proteins solubilized by trypsin contained some components of the mixed-function oxidase including all of the NADPH cytochrome *c* reductase and a part of the cytochrome P-450 (as cytochrome P-420). The trypsin digestion appears to peel off the superficial proteins of the microsomal vesicle and to uncover UDP-glucuronyltransferase from the deep layers of the microsomal membrane.

1779 DISPLACEMENT OF ALBUMIN-BOUND BILIRUBIN BY INJECTABLE DIAZEPAM PREPARATIONS IN VITRO.

(E.) Bratlid, D.; Langslet, A. (Rikshosp., Oslo, Norway). *Acta Paediatr. Scand.* 62(5):510-512, 1973.

The injectable diazepam preparations, Valium, Stesolid, and Vival were tested for their ability to displace bilirubin from albumin *in vitro*. Valium and Stesolid caused marked displacement of bilirubin and this effect was potentiated by a reduction in pH. Both these diazepam preparations contain benzoate in the buffer preservative. Vival, which does not contain benzoate in the buffer preservative, did not show any displacement at pH 7.4 and had only a slight effect at pH 6.8. The ability of benzoate as a potent displacer of bilirubin from albumin must suggest the possibility of untoward effects of Valium and Stesolid in the neonate with hyperbilirubinemia and the tendency to acidosis. It is suggested, therefore, that, in neonatal medicine, preparations not containing benzoate should be preferred for parenteral administration in cases where exact knowledge of the serum levels of benzoate after administration is not available.

1780 EFFECTS OF SPIRONOLACTONE ON CARBON TETRACHLORIDE HEPATOTOXICITY.

(E.) Carlson, G. P.; Fuller, G. C.; Fausto, N. (Coll. Pharm., Univ. Rhode Island, Kingston). *Proc. Soc. Exp. Biol. Med.* 145(1):182-185, 1974.

Pretreatment of male albino Charles River rats with spironolactone resulted in protection against CCl_4 hepatotoxicity. This protection was evidence by decreased reduction of liver glucose-6-phosphatase activity, smaller rises in SGOT and SGPT, and less severe hepatic damage as observed by histological examination. Spironolactone pretreatment and spironolactone *in vitro* both decreased lipid peroxidation due to CCl_4 as measured by malonaldehyde formation. The data substantiate the results previously reported by others that pretreatment with spironolactone of male rats results in increased cytochrome c reductase activity but no alteration in P-450 content.

1781 X-IRRADIATION AND BILIARY SECRETION IN THE RAT.

(Fr.) Deby, C.; Dupont, G.; Neuray, J.; Jeuniaux, F. (Lab. Radiobiol., Univ. Liege, Belgium). *Arch. Int. Physiol. Biochim.* 81(3):542-544, 1973.

To determine what causes an increase in fecal lipid excretion after lethal irradiation, bile secretion was investigated in fasting 8-month-old rats under pentobarbital sodium and hyosciamine anesthesia after irradiation with 1000 r. Bile output was measured in 47 males (18 controls and 29 irradiated rats) and 42 females (15 controls and 27 irradiated rats). Bile output increased in both males and females 24 and 48 hr after lethal irradiation. Lipid outputs, measured in 12 controls and 17 irradiated males, were 5.4 ± 0.43 mg/hr in controls, 13 ± 1.48 mg/hr 24 hr after irradiation, and 17.4 ± 1.66 mg/hr 48 hr after irradiation. The output of aliphatic fatty acids was 191% of control values 24 hr after irradiation and 239% of control values 48 hr after irradiation.

1782 BIOCHEMICAL STUDY OF THE DECREASED HEPATOTOXICITY OF CARBON TETRACHLORIDE AFTER LOADING THE RETICULOENDOTHELIAL SYSTEM OF THE RAT WITH CARBON PARTICLES.

(Fr.) Reynier, M.; Sireix, R.; Leterrier, F.; Mariaud, J. F. (Inst. Physicochem. Biol., Paris, France). *J. Pharmacol. (Paris)* 4(2):181-188, 1973.

Injection of 2 doses of India ink (8.6-86.5 mg/kg i.v. each) on the 2 days prior to administration of a toxic dose of carbon tetrachloride (0.75-1.25 ml/kg p.o. through a stomach tube) to male Charles River rats inhibited increases in SGPT and hepatic calcium. Two doses of 43.2 mg/kg carbon each had no appreciable effect on the decrease in glucose-6-phosphatase activity or on the relative weight of the liver. This dose of carbon significantly increased the sleeping time induced by hexobarbital (80 mg/kg i.p.) 24 hr after the last injection of carbon particles and significantly reduced the cytochrome P-450 content of the liver and the rate of ethylmorphine demethylation *in vitro* by liver microsomes. These findings suggest that carbon loading reduces the hepatotoxicity of carbon tetrachloride by reducing toxic free radical ($CCl_3^{\bullet}$) formation catalyzed by microsomal enzymes which are dependent upon cytochrome P-450.

1783 EFFECT OF ALCOHOL ON ALBUMIN SYNTHESIS BY THE ISOLATED PERFUSED RAT LIVER.

(E.) Kirsch, R. E.; Frith, L. O.; Stead, R. H.; Saunders, S. J. (Dept. Med., Univ. Cape Town, South Africa). *Am. J. Clin. Nutr.* 26(11):1191-1194, 1973.

Albumin synthesis by the isolated perfused liver of male albino Wistar rats was measured by the (^{14}C) carbonate method using perfusates of whole rat blood with and without the addition of 400 mg/100 ml alcohol. Alcohol significantly reduced albumin synthe-

ı. The addition of a mixture of 11 essential
.no acids to 10 times their normal plasma concen-
ıtions restored albumin synthesis to normal in
presence of 400 mg alcohol. Omission of trypto-
ın from the amino acid mixture did not affect
ability of amino acids to restore albumin synthe-
to normal. Methylene blue corrected the NAD/NADH
:io which had been distorted due to alcohol, but
not reverse the effects of alcohol on albumin
ıthesis. These results suggest that the disordered
/NADH ratio does not play an important role in
depression of albumin synthesis due to alcohol.

34 EARLY ULTRASTRUCTURAL CHANGES OCCURRING
IN HEPATOCYTE NUCLEI IN MICE DURING ACUTE
ENERATIVE HEPATITIS INDUCED BY FV$_3$ (FROG VIRUS 3).
.) Bingen, A.; Kirn, A. (Fac. Med., Louis Pas-
r Univ., Strasbourg, France). *J. Ultrastruct.*
. 45(5/6):343-355, 1973.

ra-thin liver slices from inbred IC mice were
mined under the electron microscope during the
st 5 hr after i.p. injection of 5 x 10^8 focus-
ming U of frog virus 3 (FV3). Lesions, which
an to appear after 1 hr, included changes in the
pe of the nuclei, an increase in perinucleolar
omatin, and an increase in the number of peri-
omatin granules. In the nucleoplasm there was
increase in the number of interchromatin granules,
ch were found in dense clusters, and fibrillar
dles appeared. Typical nucleolar segration was
ely observed. After 5 hr no changes had occurred
the cytoplasm. These results show that FV3
ses very early, pronounced changes in the nuclei
hepatocytes. Since it was previously found that
also produces very early, pronounced inhibi-
n of RNA synthesis, it is suggested that the
rastructural changes occurring in the nuclei
hepatocytes are the result of metabolic disorders.
se metabolic disorders are probably caused by
action of toxic proteins which make up recently
ubilized virus. FV3 is the first known example
a virus which induces very early, pronounced
nges in the hepatocytes in the absence of repli-
ion.

5 MITOCHONDRIAL FUNCTIONS IN AN ETHANOL-
INDUCED FATTY LIVER. *(E.)* Gordon, E. R.
ntreal Gen. Hosp., Canada). *J. Biol. Chem.*
(23):8271-8280, 1973.

ked alterations in the functions of hepatic mito-
ndria were observed in male Sprague-Dawley rats
a nutritionally adequate diet having 36% of its
oric content supplied by ethanol. A direct
sal relation exists between changes in mito-
ndrial function and abnormal accumulation of
ld in the liver. When ethanol forms a signifi-
t part of the diet, the reducing equivalents re-
red for the respiratory chain arise mainly from
lation of ethanol rather than β oxidation of
ty acids. Thus it would appear that a change
the major source of extra-mitochondrial NADH
luced a shift in fatty acid metabolism which
ms to be the basis for the biochemical change
lucing the observed alterations in mitochondrial
function. A significant increase in the hepatic level of long chain acyl coenzyme A derivatives of fatty acids was observed and it is suggested that this abnormal accumulation of these derivatives inhibited the translocation of ADP across the mitochondrial membrane. This explains the lowering of the respiratory activity and lack of respiratory control which has been observed in the mitochondria isolated from an ethanol-induced fatty liver. This transition from State 3 to 4 in the mitochondria explains the observed decrease in the flux of substrate through the tricarboxylic acid cycle, the shift in the oxidation-reduction state of the mitochondria to a more reduced level, and the decreased synthesis of ATP in the liver of these animals exhibiting a fatty liver.

1786 REGENERATION AND METABOLIC CHANGES FOLLOWING EXTENSIVE LIVER RESECTION IN DOGS. *(E.)* Flatmark, A.; Ro, J. S.; Jakobsen, Jr., A.; Enge, I.; Skrede, S. (Inst. Surg. Res., Oslo, Norway). *Scand. J. Gastroenterol.* 8(7):609-613, 1973.

Resection of 76% of the liver on an average or sham operation was performed in dogs. A midline abdominal incision was performed and the hepatic vessels were dissected out. All liver tissue, except the right lateral and caudate lobes, were removed after ligation of the appropriate afferent vessels and bile ducts. The corresponding liver veins were closed with continuous suture. The gallbladder was emptied and the resected specimen weighed. The amount of resected liver tissue in percent was then calculated. The extent of liver resection varied between 63 and 87%. Weekly blood samples were taken for metabolic studies. The 12 dogs which were killed 2 weeks or more after resection had regenerating livers which exceeded the calculated preoperative weights. Following liver resection, the total protein level in serum had increased even after 1 week, and the highest value, 7.1 g/dl, was found after 3 weeks. Albumin concentration was moderately reduced from 2.7 to 2.5 g/dl during the first 2 weeks. Albumin synthesis was therefore not seriously compromised in dogs if 3/4 of the liver were removed. The alkaline phosphatase level rose to a high of 544 U/l, while bilirubin alterations were small, probably owing to a clinically unimportant obstruction of small bile ducts. This technique probably minimizes the leakage of albumin from the liver surface.

1787 EFFECT OF ALBUMIN CONCENTRATION AND COLLOID OSMOTIC PRESSURE ON ALBUMIN SYNTHESIS IN THE PERFUSED RAT LIVER. *(E.)* Dich, J.; Hansen, S. E.; Thieden, H. I. D. (Dept. Biochem., Univ. Copenhagen, Denmark). *Acta Physiol. Scand.* 89(3): 352-358, 1973.

The effect of the albumin concentration and the colloid osmotic pressure on the rate of albumin synthesis was investigated in the perfused liver from female Wistar rats. A change in the albumin concentration from 60 mg/ml to 45 mg/ml, which resulted in a concomitant decrease in the colloid osmotic pressure, enhanced the rate of albumin synthesis by

60% from 1.4 to 2.2 mg/hr/100 g rat. A further decrease in albumin concentration to 25 mg/ml decreased the rate of synthesis to 1.8 mg/hr. A decrease in the protein concentration from 72 to 36 mg/ml increased the rate of albumin synthesis by 38%, from 1.4 to 2.0 mg/hr. Further reduction of 18 mg/ml caused a total increase in the rate of albumin synthesis of 86%. Simultaneously the colloid osmotic pressure decreased from 30.9 to 5.1 cm water. Addition of bovine gammaglobulin (72 mg/ml) to diluted plasma increased the protein concentration from 37 to 108 mg/ml and from 18 to 90 mg/ml. Colloid osmotic pressure increased simultaneously to 29.0 and 16.1 cm water, resp. This resulted in a decrease in the rate of albumin synthesis by 30% and 19%, resp. It is concluded that the rate of albumin synthesis may be regulated by the colloid osmotic pressure. The albumin concentration seems significant in such regulation only through its contribution to the colloid osmotic pressure.

1788 BILE SALTS: A DETERMINANT OF THE BILE-PERITONEAL ELECTRICAL POTENTIAL DIFFERENCE IN THE RAT. *(E.)* Binder, H. J.; Boyer, J. L. (Yale Univ. Sch. Med., New Haven, Conn.). *Gastroenterology* 65(6):943-948, 1973.

The electrical potential difference between bile and peritoneal cavity of male Sprague-Dawley rats was determined to study the mechanism of bile formation. A significant negative (-4.4 mv) was measured in the basal state at a time when the rat was secreting normal amounts of bile salts. The i.v. administration of sodium dehydrocholate produced a significant increase in negative potential difference, bile salt concentration (from 26.6 to 43.5 n moles/min), bile salt output (from 48.8 to 213.5 n moles/min/g liver), and bile flow (from 1.80 to 4.97 liters/min/g liver). When non-bile salt dependent canalicular secretion was studied by creating a biliary fistula, there was a marked fall in potential difference, bile salt concentration, and bile salt output, but only a modest decrease in bile flow. The changes observed in electrical potential difference correlated best with changes in bile salt concentration. The potential difference fell toward zero when non-bile salt dependent canalicular secretion was predominant. If the measured potential difference reflects canalicular events, non-bile salt dependent canalicular secretion may be associated with zero potential difference in the rat. The zero potential difference suggests that this fraction of canalicular secretion may be linked to a neutral cation-anion pump.

1789 EFFECT OF TAURINE ON THE CAPACITY OF THE BILE TO SOLUBILIZE CHOLESTEROL IN LITHOGENIC HAMSTERS. *(E.)* Fujihira, E.; Ohshima, T.; Ushioda, I.; Furuhashi, T.; Takahashi, N.; Sasajima, M.; Tanaka, I. (Taisho Pharmaceutical Col., Ltd., Tokyo, Japan). *Chem. Pharm. Bull.* 21(12):2796-2798, 1973.

The effect of administered taurine on gallstone formation and cholesterol solubility in bile was studied in lithogenic male golden hamsters. They were divided into 4 groups of 7 animals each and given subcutaneously taurine in the daily doses of 0, 250, 500, and 1000 mg/kg, respectively, during the entire experiment. Seven hamsters of the same lot were given free access to a commercial diet. Retardation of growth was observed in the animals fed the test lithogenic diet and daily administrations of taurine were without effect. Taurine treatment had no effect on the frequency of gallstone formation. Nevertheless, dark green-brown stones of irregular shape were developed mostly in the highly dosed groups, while white or yellow stones were characteristic in the animals treated at 250 mg/kg and the untreated. Lithogenic hamsters demonstrated a marked decrease in the biliary secretion of total bile acids, especially of cholic acid as compared to normal controls. In the taurine-treated groups of lithogenic animals, however, the reduction of bile acid secretion was to a lesser extent as the doses were increased. Organic phosphorous was also reduced markedly in the bile of lithogenic hamsters, while the biliary secretion of cholesterol increased about two times larger than the normal level. Following the administration of taurine, the reduced secretion of organic phosphorous increased slightly, while the level of cholesterol remained unchanged. Taurine treatment had no effect on the concentrations of serum cholesterol, phospholipids, and triglycerides in lithogenic animals. It is concluded that taurine treatment was ineffective in protecting animals from gallstone formation.

1790 LIVER ARTERIALIZATION WITH PORTACAVAL SHUNT IN THE CIRRHOTIC RAT. *(E.)* Lecompte, Y.; Franco, D.; Martin, E. D.; Bismuth, H. (Paul Brousse Hosp., Villejuif, France). *Surgery* 75(2):161-168, 1974.

Hepatic cirrhosis was induced in 29 male Charles River rats by carbon tetrachloride (0.1 ml, s.c.) given twice weekly for 8 months. End-to-side portacaval shunts were performed on 10 rats while 19 others had portacaval shunts plus arterialization of the hepatic stump of the portal vein with the use of the right renal artery. The mortality rate within 24 hr of operation in the arterialized group was 57%; in the shunted group, 33%. There was a steady weight loss in both groups. SGPT increased to 313 mU/ml on the second day in shunted animals and thereafter returned to preoperative values within a week. SGPT did not rise in arterialized animals. The BSP disappearance rate decreased to 0.084 in the shunted rats on the 7th postoperative day, compared to the preoperative value of 0.123. Similar results were obtained in the arterialized animals, though the decline in disappearance rate was much slower. The hepatic structure in shunted animals remained unchanged from its cirrhotic state even 6 weeks after shunting. In arterialized rats, however, changes including increases in portal fibrosis, spotty necrosis, polymorphonuclear infiltration of the portal tracts, and dilation of the intrahepatic portal branches with a thickening of their walls were noted even after 2 weeks. It is suggested that, in cirrhotic patients following portacaval shunting, the disappearance of portal blood is not compensated by a spontaneous increase in liver

rterial blood flow, thus arterialization may be
seful in overcoming the early postoperative risk
f liver failure. However, liver damage as seen
n this study may be due to the high rate flow
nd/or the high pressure created within the portal
ystem by the arterioportal anastomosis, and would
orce consideration of arterialization as only a
emporary procedure.

791 INFLUENCE OF ARGININE OR ORNITHINE UPON ETHANOL EFFECTS ON RAT LIVER METABOLISM.

E.) Griffaton, G.; Rozen, R.; Naon, R.; Lowy, R.
Hosp. Bichat, Paris, France). *Enzyme* 14(6):325-
39, 1972/73.

oung Wistar male rats (120-130 g) were fasted over-
ight and given either 3 g ethanol/kg body weight,
5 g/kg arginine, 1.14 g/kg ornithine, or the asso-
iation of ethanol and arginine, or ethanol and or-
ithine by the i.p. method. The animals were killed
: 0 (controls), 20, 40, and 60 min after the injec-
ion. The time course of 13 compounds was followed
n their liver. After arginine or ornithine adminis-
ration, glutamate, aspartate, alanine, malate, cit-
ate, and urea increased, while the ketone bodies,
-hydroxybutyrate, and acetoacetate decreased. The
oncentrations of α-oxoglutarate, pyruvate, and
aloacetate did not change. The changes produced
ethanol were those presented in previous papers,
t there were interactions when ethanol was given
gether with arginine or ornithine: they chiefly
ncerned alanine, citrate, and acetoacetate in the
nithine experiment, aspartate, glutamate, gluta-
ne, and urea in the arginine one. Arginine or
nithine promote a strong influx of metabolites from
utamate to malate, aspartate, and alanine. This
obably decreases citrate synthesis from ethanol
d overcomes ethanol effects at the α-oxoglutarate
vel. Ornithine was less efficient than arginine.
rhaps this is related to differences in urea and
monia concentration changes in the 2 experiments.

92 THE EFFECT OF TAUROCHOLATE ON THE BILIARY SECRETION OF THYROXINE IN THE RAT LIVER.

.) Hillier, A. P. (Physiol. Lab., Cambridge,
gland). *Endocrinology* 94(1):272-275, 1974.

e secretion of thyroxine into bile by the perfused
t liver is autoregulated--a rise of 2 μg in the
yroxine content of the tissue causes, at its peak,
10-fold increase in the fractional rate of secre-
on. However, if taurocholate is omitted from the
rfusion fluid, the increase is only 1-2 fold.
bsequent addition of bile salt causes a sharp rise
the biliary thyroxine concentration, and injec-
ons of only 25 μg taurocholate stimulate thyroxine
cretion without altering bile flow. The effect
dose dependent and is present at normal concen-
ations of thyroxine but is most pronounced in the
per physiological range. Unlike that of thyroxine,
e concentration of triiodothyronine in bile is
affected by the presence of taurocholate in the
rfusion fluid. It is suggested that thyroxine
ut not triiodothyronine) is being selectively
absorbed from the biliary tract back into the liver
ll, and that taurocholate and high concentrations
of hormone 'stimulate' thyroxine secretion by reducing the proportion which is reabsorbed.

1793 THE EFFECT OF INTERRUPTION OF THE ENTEROHEPATIC CIRCULATION OF BILE ACIDS AND OF CHOLESTEROL FEEDING ON CHOLESTEROL 7α-HYDROXYLASE IN RELATION TO THE DIURNAL RHYTHM IN ITS ACTIVITY.

(E.) Mitropoulos, K. A.; Balasubramaniam, S.; Myant, N. B. (Hammersmith Hosp., London, England). *Biochim. Biophys. Acta* 326(3):428-438, 1973.

Cholesterol 7α-hydroxylase activity was assayed by a direct method in liver microsomal preparations from male Wistar rats adapted to controlled lighting and feeding and subjected to conditions known to modify hepatic synthesis of cholesterol and bile acids. The mass of microsomal cholesterol that acts as substrate for the enzyme (the substrate pool) was estimated in each set of conditions. In cholestyramine-fed and bile-fistula rats, the activity of the enzyme was increased, but the normal diurnal rhythm in activity was maintained. The size of the substrate pool was not increased in the treated animals. In bile-fistula rats the biliary excretion of bile acids and cholesterol assumed a diurnal rhythm in the activity of cholesterol 7α-hydroxylase and in the rate of synthesis of cholesterol in the liver. When cholesterol was added to the food, cholesterol 7α-hydroxylase activity was increased but enzyme activity continued to vary diurnally. Cholesterol feeding increased the size of the substrate pool, suggesting that the increase in activity may be due to an increase in the supply of substrate, rather than to increased capacity of the enzyme.

1794 INVESTIGATIONS OF THE ENTEROBILIARY METABOLISM OF LECITHIN.

(E.) Tompkins, R. K.; King III, W. (Univ. California, Sch. of Med., Los Angeles). *Surgery* 75(2):243-252, 1974.

Simultaneous sampling in pigs of thoracic duct lymph, portal and vena caval blood, and common duct bile after intestinal administration of ^{14}C-lecithin revealed a rapid and progressive rise in the concentration of radioactivity in lipid fractions of the bile extracts. Analyses of the distribution of lipid radioactivity demonstrated triglycerides to be the major form of transport in lymph and blood, whereas 70% of the radioactivity in bile was in the lecithin (phosphatidyl-choline) fraction 8 hr after isotope administration. The data demonstrate that dietary lecithin contributes to biliary lecithin secretion probably by way of its intestinal hydrolytic products. Animals with intact thoracic ducts showed the same cumulative rise in biliary lipid radioactivity as did those with thoracic duct fistulas, suggesting that the intestinal precursors of biliary lecithin synthesis may reach the liver by a route other than the thoracic duct.

1795 INDUCTION OF UDP GLUCURONYLTRANSFERASE IN THE LIVER AND EXTRAHEPATIC ORGANS OF THE RAT.

(E.) Aitio, A. (Dept. Physiol., Univ. Turku, Finland). *Life Sci.* 13(12):1705-1713, 1973.

Extrahepatic UDP glucuronyl transferase was studied in male Wistar rats. UDP glucuronyltransferase (4-methylumbelliferone) activity was enhanced in the liver of the rat after administering phenobarbital, cinchophen or 3-methylcholanthrene, in the lung after administration of cinchophen or 3-methylcholanthrene, and in the kidney after cinchophen. The UDP glucuronyltransferase of the spleen could not be induced with the dosage of the drugs used. Chlorpromazine was not able to induce either hepatic or extrahepatic UDP glucuronyltransferase. Chlorpromazine competitively inhibited hepatic UDP glucuronyltransferase *in vitro*. It is concluded that the capability to form glucuronides and to increase the capability seem to be widely distributed in the tissues of laboratory animals. Capacity of a chemical to induce mixed function oxidase does not necessarily correlate with capacity to induce UDP glucuronyltransferase.

1796 COMPARTMENTATION OF THE EARLY STEPS OF CHOLESTEROL BIOSYNTHESIS IN MAMMALIAN LIVER. *(E.)* Decker, K.; Barth, C. (Fac. Med., Univ. Freiburg, Breisgau, Germany). *Mol. Cell. Biochem.* 2(2):179-188, 1973.

Cholesterol synthesis was studied in the isolated perfused rat liver and with cell-free preparations by incorporation measurements of ^{3}H from ^{3}HOH and of carbon label from [1-^{14}C]-acetate. The following specific inhibitors were used: (-)-hydroxycitrate, kynurenate, and avidin. Fatty acid and cholesterol biosynthesis share a common substrate pool of cytoplasmic acetyl-CoA. The substrate of mevalonate synthesis is furnished by an extramitochondrial pathway of β-hydroxy-β-methylgluraryl-CoA synthesis, which does not include malonyl-CoA. This favors the assumption of a sequence including cytoplasmic thiolase and β-hydroxy-β-methylglutaryl-CoA synthase. Besides its inhibitory action on ATP citrate lyase (-)-hydroxycitrate was found to stimulate acetyl-CoA carboxylase. Acetyl-CoA synthetase activity of liver is localized predominantly in the cytoplasm. The regulatory behavior of the cytoplasmic enzyme points to a lipogenetic function. The cytoplasmic enzyme directs acetate into fatty acid and cholesterol synthesis. Its activity and regulatory behavior fit into an acetate pathway of acetyl group transfer. The expenditure of pyrophosphate bond energy per C_2-unit transferred is the same if the acetate pathway and the citrate-malate cycle are compared. In some situations, however, acetate as a diffusible metabolite may be a more readily available C_2-precursor than citrate. The activity and the regulatory behavior of the extramitochondrial acetyl-CoA synthetase necessitates a reconsideration of the mechanisms which supply acetyl-CoA to the cytoplasmic compartment for both fatty acid and cholesterol biosynthesis.

1797 GLUCOSE REABSORPTION FROM BILE. EVIDENCE FOR A BILIOHEPATIC CIRCULATION. *(E.)* Guzelian, P.; Boyer, J. L. (Yale Univ. Sch. Med., New Haven, Conn.). *J. Clin. Invest.* 53(2):526-535, 1974.

To study the mechanisms of this blood-bile glucose concentration difference, infusions of glucose were administered i.v. to 300-400 g male Sprague-Dawley rats with ligated renal pedicles and to 2 postcholecystectomy patients with indwelling t-tubes. Glucose was assayed in plasma, bile, and rat liver by a hexokinase method specific for D-glucose. In man, glucose was detected in bile when plasma glucose increased above 350 mg/100 ml. When plasma concentrations increased between 400 and 900 mg/100 ml, glucose appeared more rapidly in bile, defining by extrapolation an apparent plasma glucose threshold of 280 mg/100 ml. Intraportal phlorizin, a competitive inhibitor of glucose transport, significantly increased bile glucose concentrations. Plasma-bile concentration differences were also observed in rats after i.v. [3-^{14}C]*O*-methyl glucose (3-*O*-MG) but not after [^{3}H]mannitol. Hepatic glucose levels were never lower than plasma levels and liver-plasma 3-*O*-MG ratios were 0.92 indicating that entry of glucose and 3-*O*-MG into hepatocyte water was not limiting. Furthermore, when sodium dehydrocholate augmented canalicular secretion, biliary glucose excretion increased proportionally suggesting that glucose entry into bile was not impeded. Biliary glucose excretion, increased progressively when estimated hepatic glucose secretion rates exceeded 50 μg/min or when phlorizin was given. Finally, during bile stop-flow experiments, [3-^{14}C]*O*-MG and [^{14}C]glucose were selectively removed from bile compared with [^{3}H]mannitol. The findings suggest that glucose and 3-*O*-MG are reabsorbed from bile after entry at the hepatocyte, accounting for their low bile-plasma ratio. The biliary glucose transport process may be described by Michaelis-Menten kinetics and is analogous to recently defined kinetics for renal tubular reabsorption of glucose. These studies provide evidence that certain products of bile secretion may undergo a "biliohepatic" circulation.

1798 REDUCED SYNTHESIS OF HEPATIC MICROSOMAL CYTOCHROME P_{450} IN THE BILE DUCT LIGATED RAT. *(E.)* Mackinnon, A. M.; Simon, F. R. (Univ. Colorado Med. Ctr., Denver). *Biochem. Biophys. Res. Commun.* 56(2):437-443, 1974.

Cholestasis produced by bile duct ligation was associated with a 50% reduction in hepatic microsomal cytochrome P_{450} content in male Sprague-Dawley rats. Tentative identification of cytochrome P_{450} in washed microsomal fractions was achieved on SDS-urea polyacrylamide gels by its physical properties, half-life and response to pharmacologic agents. The relative synthesis rate of P_{450} apoprotein, determined by a double isotope method, was significantly reduced 3 days after bile duct ligation. P_{450} apoprotein degradation was markedly reduced, with the half-life increasing from 24 to 50 hr. These data indicate that a reduced rate of synthesis, rather than increased degradation, is responsible for reduction of P_{450} in cholestasis.

1799 PARADOXICAL INCREASE IN RATE OF CATABOLISM OF LOW-DENSITY LIPOPROTEINS AFTER HEPATECTOMY. *(E.)* Sniderman, A. D.; Carew, T. E.; Chandler, J. G.; Steinberg, D. (Med. Sch., Univ. California San Diego, La Jolla). *Science* 183(4124):526-528, 1974.

e effect of hepatectomy on the rate of catabolism
 low-density lipoproteins was studied. Blood was
awn from donor swine (Hormel white or miniature)
ighing 30 to 50 kg. Low-density lipoprotein was
acted with ^{125}ICI. The (^{125}I) low-density lipo-
otein was reisolated and sterilized. Experimental
imals were fasted overnight and catheters were
serted in both external jugular veins. A tracer
se of (^{125}I) low-density lipoprotein (less than
 mg of low-density lipoprotein) was injected;
asma samples were obtained and radioactivity was
asured. Less than 2% of the radioactivity was
 the lipid moiety and more than 98% was precipi-
ble with trichloroacetic acid. Reisolation of
w-density lipoproteins from plasma at various in-
rvals after injection showed that 95% or more of
e plasma ^{125}I remained in the fraction. Six days
ter, the animal was anesthetized, the liver was
moved and venous return from the viscera was main-
ined. The disappearance curves from the control
udies were resolved into 2 exponential components
ing least-squares fitting procedures. The average
rrelation coefficients for the least-squares re-
ession lines were 0.974 for the first phase and
984 for the second phase. The half-lives of the
rst (faster) and second (slower) exponentials were
termined from their slopes. The fractional cata-
lic rate was calculated from the slopes and the
ro time intercepts. After hepatectomy, strictly
noexponential disappearance curves were observed
d fitted by using least-squares regression lines.
e average correlation coefficient for these was
995. After hepatectomy, total low-density lipo-
otein levels fell progressively and the rate of
sappearance of low-density lipoproteins was the
me as that for the disappearance of ^{125}I. These
sults in hepatectomized animals strongly support
e conclusions drawn from tissue distribution
udies that the liver represents the major extravas-
lar pool of low-density lipoproteins. It is pro-
sed that the liver (or some function requiring an
tact liver) may affect the metabolism of low-den-
ty lipoproteins in a manner that prolongs its
fetime in the plasma compartment.

00 HISTOCHEMICAL STUDY OF GAMMA GLUTAMYL
TRANSPEPTIDASE (GGT) IN EXPERIMENTAL INTRA-
PATIC AND EXTRAHEPATIC CHOLESTASIS. *(E.)* Ronchi,
; Desmet, V. J. (Acad. Hosp. St. Rafael, Lueven,
lgium). *Beitr. Pathol.* 150(3):316-321, 1973.

istochemical study of Gamma glutamyl transpeptidase
GT) was performed on male Wistar rat liver in ex-
rimental extra- and intrahepatic cholestasis, the
ter induced by Norethandrolone. Intrahepatic
olestasis is characterized by the appearance of GGT
tivity at the canalicular membranes of periportal
renchymal cells; the intensity of the staining reac-
on is relatively dose dependent and rapidly rever-
ble. Extrahepatic cholestasis is characterized by
 early increase of GGT in ductular cells, with con-
mittant appearance of positive staining on the
teral cell membranes of the biliary lining cells.
sitive staining of liver parenchymal cells appears
ly after several days. In comparison with findings
 intrahepatic cholestasis, this is interpreted as the
flection of a superimposed intrahepatic cholestasis produced by the accumulation of biliary constituents in the parenchymal cells. It is concluded that a ductular alteration of the GGT histochemical pattern points towards an extrahepatic cholestasis, whereas a definite increase in parenchymal GGT activity points towards an intrahepatic biliary secretory failure.

1801 HISTOCHEMICAL STUDY OF SO-CALLED "MARKER ENZYMES OF CHOLESTASIS" DURING EXTRAHEPATIC BILE DUCT OBSTRUCTION IN THE RAT. *(E.)* Ronchi, G.; Desmet, V. (St. Rafael Univ. Hosp., Louvain, Belgium). *Beitr. Gerichtl. Med.* 149(3):213-226, 1973.

The histochemical location of gamma glutamyltranspeptidase, leucine aminopeptidase and non-specific alkaline phosphatase was studied in livers of normal rats and of rats with ligated common bile ducts. In normal rat liver gamma glutamyl transpeptidase activity was present at the apical border of the lining cells of bile ducts and ductules. During the first days of cholestasis, original bile ducts and proliferating ductular structures showed a strong positive reaction; enzyme activity was concentrated at the apical pole and at the lateral membranes of the cells. After obstruction of more than 1 week, periportal hepatocytes also presented slight enzyme activity. In normal rat liver leucine aminopeptidase showed a weak positive canalicular pattern. Some portal biliary structures were also positive. After bile duct ligation, the canalicular activity rapidly decreased, whereas the ductular activity increased strongly. Some canaliculi in a narrow periportal area were positive after incubation for alkaline phosphatase. After 1 day of obstruction, all sinusoidal, canalicular and lateral membranes of the parenchymal cells were positive. This decreased from the third day on, but all during the experiment alkaline phosphatase activity remained higher than in control animals. These histochemical results correlated with changes in serum concentrations of these enzymes supporting the hypothesis that variations in liver enzymatic activity directly determine variations in serum levels during extrahepatic obstruction. Further, the liver enzyme activity results from the stimulating effect of cholestasis, causing overproduction and regurgitation of these enzymes into the blood stream.

1802 UTILIZATION OF ADENOSINE AS A TOOL IN STUDIES ON THE REGULATION OF LIVER GLYCOGEN BIOSYNTHESIS. *(E.)* De Sanchez, V. C.; Brunner, A.; Sanchez, M. E.; Lopez, C.; Pina, E. (Fac. Med., Univ. Natl. Autonoma, Mexico City, Mexico). *Arch. Biochem. Biophys.* 160(1):145-150, 1974.

875 SOME OBSERVATION ON THE SMALL INTESTINAL OLIGOSACCHARIDASE ACTIVITES IN NORMAL AND LLOXAN DIABETES, BEFORE AND AFTER INSULIN THERAPY. *E.)* Sharma, A. K.; Ghosh, A. K. (Calcutta Univ., ndia). *Japan. J. Exp. Med.* 43(5):443-446, 1973.

tudies on intestinal oligosacchardidase activity in normal and alloxan diabetes before and after insulin therapy have been done on albino rats. In alloxan diabetes, the activities of lactase, sucrase, and maltase were stimulated by 59.6%, 7.3%, and 31.4% respectively. After insulin therapy (2 units/100 g i.m. for 12 days) the lactase activity was reduced to 23.3% but sucrase and maltase activities were further stimulated by 40.5% and 37.8%, respectively. In normal rats after prolonged insulin therapy (2 units/100 g i.m. for 12 days), the lactase, sucrase, and maltase activities were stimulated by 41%, 46.6%, and 45.7%, respectively. The stimulation of lactase activity in alloxan diabetes was further proved by lactose absorption test in rabbits. There was much elevation of lactose absorption in alloxan diabetes, and after insulin therapy (5 units/kg of body weight) the lactose absorption was greatly reduced.

nguli, P. C.; Care, A. D. (Dept. Anim. Physiol.,
iv. Leeds, England). *J. Endocrinol.* 59(2):217-
), 1973.

e role of calcitonin in postprandial calcium
neostasis was studied in young pigs. When pigs
re fasted for more than 36 hr and then fed, the
asma calcium concentration decreased by 6.1% over
-120 min. In thyroidectomized pigs the plasma
lcium concentration increased by 7.2% when they
re fed after a 36 hr fast. It is therefore sug-
sted that increased calcitonin secretion assists
the control of postprandial hypercalcemia. Di-
t measurement of calcitonin in peripheral plasma
pported this suggestion. The plasma calcium con-
ntration in an intact pig on a normal feeding
gime does not change after a meal and thus the
ssibility of the involvement of one or more humoral
ctors in the stimulation of thyroid C-cells was
vestigated. Exogenous and endogenous gastrin
imulated by meat extract increase calcitonin
cretion rate. This observation can now include
her stimuli to endogenous gastrin, e.g. glycine
l gastric distension. Furthermore, partially
rified enteroglucagon increased calcitonin secre-
n rate from perfused thyroid glands, isolated
situ. Stimulation of endogenous enteroglucagon
the intraduodenal administration of glucose, and
bable stimulation of endogenous pancreozymin by intra-
denal fat, were both associated with an increased
citonin secretion rate from the thyroid gland.
se results support the existence of a gastroen-
o-thyroid C-cell system stimulating calcitonin
retion and thus protecting the skeleton from
essive bone resorption during periods of dietary
ficiency.

2 THE EFFECT OF BRADYKININ ON THE CONSECUTIVE VASCULAR SECTIONS OF THE SMALL AND
GE INTESTINE. *(E.)* Fasth, S.; Hulten, L.
d Dept. Surg., Univ. Goteborg, Sweden). *Acta
r. Scand.* 139(8):707-715, 1973.

lethysmographic technique was utilized to in-
tigate quantitatively the reactions within the
secutive vascular sections of the small and large
estine of the cat during graded intra-arterial
usion of bradykinin. Bradykinin infusion in
es that reduced vascular resistance evoked a
racteristic increase in intestinal volume, oc-
ring in 2 phases with completely different slopes.
first slope corresponded to a capacity response,
reas the second slow increase in tissue volume,
lected a continuous outward transcapillary
tration. Bradykinin infusion in doses that
e subthreshold with respect to resistance and
acitance responses still evoked a significant
rease in capillary filtration coefficient and
n the vascular smooth muscles were relaxed by
ded infusions of isoprenaline, capillary filtra-
n coefficient was considerably higher at all
od flow levels following superimposed infusions.
se observations suggest that bradykinin increases
permeability of the intestinal exchange vessels.
The vascular effects evoked by bradykinin are in many respects similar to those following activation of the pelvic nerves to the colon, and the results lend additional support to the hypothesis that kinins might be involved in the functional hyperemia of the colonic mucosa.

1893 EFFECTS OF INTESTINAL PEPTIDE MIXTURE G2 AND VASOACTIVE INTESTINAL PEPTIDE VIP ON SPLANCHNIC CIRCULATION IN THE DOG. *(E.)* Thulin, L.; Olsson, P. (Karolinska Inst., Stockholm, Sweden). *Acta Chir. Scand.* 139(8):691-697, 1973.

Splanchnic circulatory effects of the peptide mixture G2, which is derived as a late side-fraction during the preparation of secretin, and the vasoactive intestinal peptide VIP, which is the result of further purification of the G2 fraction, were studied in 10 anaesthetized mongrel dogs. Using electromagnetic flowmeters, blood flows were measured in the hepatic artery proper, the superior mesenteric artery and the portal vein. Cholecystectomy was performed. Systemic, caval and portal pressures were recorded. Vascular resistances were calculated. Group I: Four dogs were given 13 caval and 13, portal 1-min infusions of peptide mixture G2 in 2 dosages, ranging from 0.3 to 4.0 μg/kg/min. Group II: Six dogs were given 24 caval and 24 portal 1-min infusions of VIP in 2 dosages, ranging from 0.03 to 0.45 μg/kg/min. The systemic blood pressure fell with 1-23 mmHg. The blood flow increased with a maximum of approximately 50% in the hepatic artery proper and 30% in the portal vein. It remained unaffected or decreased slightly in the superior mesenteric artery. The vascular resistance decreased, indicating vasodilation, with a maximum of approximately 40% in the hepatic artery proper and 10% in the portal vein. It remained unaffected or increased slightly in the superior mesenteric artery. Within the splanchnic area, the G2 and VIP action was thus highly selective. All effects appeared immediately and were of brief duration. They all showed a dose-response correlation. Caval infusion was as a rule more effective than portal, indicating partial hepatic inactivation of the substances.

1928 ION TRANSPORT ACROSS ISOLATED ILEAL MUCOSA INVADED BY SALMONELLA. *(E.)* Fromm, D.; Gianella, R. A.; Formal, S. B.; Quijano, R.; Collins, H. (Walter Reed Army Inst. Res., Washington, D.C.). *Gastroenterology* 66(2):215-225, 1974.

1929 EFFECT OF DIETARY PHOSPHORUS ON RETICULOENDOTHELIAL CLEARANCE OF SALMONELLA ORGANISMS IN ENDOTOXIN TREATED GUINEA PIGS. *(E.)* Doak, R. L.; Garner, G. B.; O'Dell, B. L. (Dept. Vet. Microbiol. Pathol., Purdue Univ., West Lafayette, Ind.). *Life Sci.* 13(7):959-968, 1973.

1930 METABOLISM AND ACUTE TOXICITY OF AFLATOXIN B_1 IN RATS. *(E.)* Purchase, I. F. H.; Steyn, M.; Gilfillan, T. C. (South African Med. Res. Council, Pretoria, South Africa). *Chem. Biol. Interact.* 7(5):283-287, 1973.

1931 PSEUDOMONAS AERUGINOSA INFECTIONS IN RATS FED ON MONOSODIUM GLUTAMATE WITH OBSERVATIONS ON THE PSEUDOMONAS FLORA IN THEIR INTESTINES. *(E.)* Miyaki, K.; Aibara, K.; Shimizu, T.; Morishita, Y.; Shimode, T.; Ito, Y. (Natl. Inst. Health, Tokyo, Japan). *Jap. J. Med. Sci. Biol.* 26(2): 59-70, 1973.

1932 ROLE OF HYDROGEN BONDING IN ORGANIC CATION DISCRIMINATION BY GALLBLADDER EPITHELIUM. *(E.)* Moreno, J. H.; Diamond, J. M. (Univ. California Med. Ctr., Los Angeles). *Nature* 247(5490):368-369, 1974.

1933 POSSIBLE PRECURSORS OF AMINOPEPTIDASE AND ALKALINE PHOSPHATASE IN THE PROXIMAL TUBULES OF KIDNEY AND THE CRYPTS OF SMALL INTESTINE OF MICE. *(E.)* Wachsmuth, E. D.; Torhorst, A. (Friedrich Miescher Inst., Basel, Switzerland). *Histochemistry* 38(1):43-51, 1974.

1934 PHOTOCHEMICAL REACTIONS IN MICELLES OF BIOLOGICAL IMPORTANCE. *(E.)* Chen, M.; Gratzel, M.; Thomas, J. K. (Chem. Dept., Univ. Notre Dame, Ind.). *Chem. Phys. Lett.* 24(1):65-68, 1974.

1935 LIVER FUNCTION IN THE PIG: 1. THE EFFECTS OF 30 MINUTES NORMOTHERMIC ISCHAEMIA. *(E.)* Battersby, C.; Hickman, R.; Saunders, S. J.; Terblanche, J. (Dept. Surg., Univ. Cape Town, South Africa). *Br. J. Surg.* 61(1):27-32, 1974.

1936 CEREBRAL BLOOD FLOW AND CEREBRAL METABOLIC RATE FOR OXYGEN IN RATS WITH PORTA-CAVAL ANASTOMOSIS. *(E.)* Eklof, B.; Holmin, T.; Johannsson, H.; Siesjo, B. K. (Univ. Hosp., Univ. Lund, Sweden). *Acta Physiol. Scand.* 90(2):337-344, 1974.

1937 CAN A HETEROTOPICALLY PLACED SEGMENTAL LIVER GRAFT BE LIFE-SUPPORTING? AN AFFIRMATIVE FINDING. *(E.)* Maki, T.; Slapak, M. (Harvard Med. Sch., Boston, Mass.). *Br. J. Surg.* 61(1):33-39, 1974.

1938 STRUCTURAL STUDY OF THE BLOOD GROUP A ACTIVE GLYCOLIPIDS OF HOG GASTRIC MUCOSA. *(E.)* Slomiany, A.; Slomiany, B. L.; Horowotiz, M. I. (New York Med. Coll., Valhalla, N.Y.). *J. Biol. Chem.* 249(4):1225-1230, 1974.

1939 INTESTINAL RESISTANCE IN THE EXPERIMENTAL ENTERIC INFECTION OF MICE WITH A MOUSE ADENOVIRUS. III. SUPPRESSIVE EFFECT OF CYCLOPHOSPHAMIDE ON THE ESTABLISHMENT AND DURATION OF THE INTESTINAL RESISTANCE. *(E.)* Hashimoto, K.; Okada, Y.; Tajiri, T.; Amano, H.; Aoki, N.; Sasaki, S. (Keio Univ. Sch. Med., Tokyo, Japan). *Jap. J. Microbiol.* 17(6):503-511, 1973.

1940 ANTIBODY RESPONSES IN RABBITS TO INJECTIONS OF WHOLE CELL, FLAGELLA, AND FLAGELLIN PREPARATIONS OF CHOLERA AND NONCHOLERA VIBRIOS. *(E.)* Smith, Jr., H. L. (Jefferson Med. Coll., Philadelphia, Pa.). *Appl. Microbiol.* 27(2):375-378, 1974.

1941 ASSOCIATION OF MICROORGANISMS WITH THE EPITHELIUM IN THE ALIMENTARY TRACT OF ASPICULARIS TETRAPTERA. *(E.)* Tannock, G. W.; Savage, D. C. (Dept. Microbiol., Univ. Illinois, Urbana). *Infect. Immun.* 9(2):475-476, 1974.

1942 VASCULARIZED TRANSPLANTATION OF THE RAT PANCREAS WITHOUT DUODENUM. *(E.)* Nozawa, M.; Weil, III., R.; McIntosh, R.: Reemtsma, K. (Columbia Univ. Coll. Physicians Surgeons, New York, N.Y.). *Transplantation* 17(1):137-140, 1974.

1943 PATHOLOGICAL CHANGES PRODUCED IN JAPANESE QUAIL BY INGESTION OF CADMIUM. *(E.)* Richardson, M. E.; Spivey Fox , M. R.; Fry, Jr., B. E. (Off. Pesticide Prog., EPA, Washington, D. C.) *J. Nutr.* 104(3):323-338, 1974.

1944 DISTRIBUTION AND ACTIVITIES OF DICARBOXYLIC AMINO ACID TRANSAMINASES IN GASTROINTESTINAL MUCOSA OF RAT, MOUSE, HAMSTER, GUINEA PIG, CHICKEN AND PIGEON. *(E.)* Volman-Mitchell, H.; Parsons, D. S. (Dept. Biochem., Univ. Oxford, England). *Biochim. Biophys. Acta* 334(2):316-327, 1974.

1945 EVIDENCE OF AN INTESTINAL FACTOR DURING PROLONGED HYPOTHERMIA IN THE RAT. *(E.)* Rink, R. D. (Dept. Anat., Univ. Louisville, Ky.). *Eur. Surg. Res.* 5(3):186-193, 1973.

1946 ACTIVITIES OF LIPID REESTERIFYING ENZYMES IN JEJUNAL MICROSOMES OF BILE FISTULA RATS. ATTEMPTS TO CORRELATE ENZYME ACTIVITIES WITH MICROSOMAL PHOSPHOLIPID CONTENT. *(E.)* Rodgers, J. B.; Tandon, R.; O'Brien, R. J. (Albany Med. Coll., N.Y.). *Biochim. Biophys. Acta* 326(3):345-354, 1973.

1947 CONTENT OF FREE AND BOUND N-ACETYLNEURAMINIC ACID IN THE KIDNEYS AND SMALL INTESTINAL MUCOSA OF ALBINO RATS DURING DEVELOPMENT. *(Rus.)* Mnatsakanian, B. A.; Adunts, G. T. (Inst. Biochem., Acad. Sci. Armenian SSR, Erevan, USSR). *Biol. Zh. Armenii* 26(10):78-80, 1973.

1948 THE DISTRIBUTION OF rb^{86} IN DIFFERENT PARTS OF THE LIVER. *(E.)* Ohnhaus, E. E. (Med. Univ. Clin., Basel, Switzerland). *Pfluegers Arch.* 346(2):157-161, 1974.

49 HYPOTONIC DUODENOGRAPHY WITH GLUCAGON.
(E.) Miller, R. E.; Chernish, S. M.;
senak, B. D.; Rodda, B. E. (Indiana Univ. Sch.
d., Indianapolis). *Radiology* 108(1):35-42, 1973.

a double blind crossover study, the effects of
mg glucagon and 1 mg atropine sulfate on duodenal
nicity and motility were compared to placebo
6 asymptomatic men (aged 20-54 yr). In a similar
udy, 2 mg glucagon and 30 mg propantheline brom-
e were compared to placebo. In 10 to 30 min after
m. administration there was a significant decrease
duodenal motility and tonicity with glucagon.
th tonicity and motility were near normal at 60
n. Responses to atropine sulfate and propantheline
omide were sometimes evident at 10, 30 and 60 min,
t were variable and not consistently greater than
th placebo. With atropine sulfate and propan-
eline bromide, intensity of reported side effects,
cluding dryness of mouth, nausea, headache,
miting, flushing, and urinary retention, was
eater than with placebo or glucagon. It was con-
uded that, in comparison to 1 mg atropine or
mg propantheline bromide, 2 mg glucagon (i.m.)
more effective and preferable for hypotonic duo-
nography.

50 A NEW ANGIOGRAPHIC TECHNIQUE IN THE DIAGNOSIS OF LIVER TUMOR. *(E.)* Wirtanen,
W. (Univ. Wisconsin Sch. Med., Madison). *Radiology*
8(1):51-54, 1973.

examination was made of 332 patients with pri-
ry and secondary liver carcinoma *via* "infusion
giography" consisting of 50 ml of contrast agent
jected selectively into the hepatic artery over
sec. This technique permits an increased con-
ntration of contrast medium in areas of neovas-
larity with a comcomitant decrease in normal
renchymal contrast staining when the portal
in clears the agent selectively from nontumor
eas, resulting in enhanced tumor visualization.
mor staining was evident in more than 97.5% of
e 332 liver angiographies. Of this 97.5%, well-
fined tumor nodules were evident in 34,3%, well-
veloped tumor vessels with intense staining in
%, and tumors comprised mainly of extremely hyper-
scular metastatic sarcomas and hepatomas were
ted in 9.3%. Selectivity and slow injection rates
hance tumor staining, the most significant criterion
diagnosing liver tumor.

51 ADENOMA OF THE EXOCRINE PANCREAS: ITS ANGIOGRAPHIC DIAGNOSIS. *(Fr.)* Piffaretti,
G.; Chapuis, G. (San Giovanni Hosp., Bellinzona,
itzerland). *Radiol. Clin. Biol.* 43(3):233-241,
74.

52 SECRETIN-PANCREOZYMIN TEST IN THE FUNCTIONAL DIAGNOSIS OF THE EXOCRINE PANCREAS. *(Ger.)*
intner, H. (1st Med. Clin., Univ. Vienna, Austria).
en. Klin. Wochenschr. 85(40):665-667, 1973.

1953 SALIVARY GLAND SCINTIGRAPHY. *(Fr.)* Tainmont, J. (Military Hosp., Brussels, Belgium). *Acta Otorhinolaryngol. Belg.* 27(4):435-463, 1973.

1954 VALUE OF LAPAROSCOPY IN THE DIAGNOSIS OF GALLBLADDER CANCER: STUDY OF 34 CASES. *(Sp.)* de Dios Vega, J. F.; Hita Perez, J.; Muro Gonzalez, J.; Cosme Jimenez, A.; Mino Fugarolas, G.; Cano Lapez, J. M. (La Paz Munic. Sanit., Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 41(8):867-874, 1973.

1955 FUTILITY OF BARIUM SULFATE IN DIAGNOSIS OF BLEEDING MECKEL DIVERTICULUM. *(E.)* Meguid, M. M.; Wilkinson, R. H.; Canty, T.; Eraklis, A. J.; Treves, S. (Children's Hosp., Boston, Mass.). *Arch. Surg.* 108(3):361-362, 1974.

1956 PHARMACORADIOLOGY OF THE GASTROINTESTINAL TRACT. *(E.)* Gohel, V. K.; Dalinka, M. K.; Mandell, G. A.; Azimi, F. (Thomas Jefferson Univ. Hosp., Philadelphia, Pa.). *CRC Crit. Rev. Clin. Raciol. Nucl. Med.* 5(1):69-107, 1974.

1957 FIBERCOLONOSCOPY. *(E.)* Yamagata, S.; Watanabe, H. (Tohoku Univ. Sch. Med., Sendai, Japan). *Am. J. Proctol.* 25(2):60-66, 1974.

1958 EMERGENCY GASTROINTESTINAL ANGIOGRAPHY. NEW TECHNICS OF CONTROLLING GASTROINTESTINAL BLEEDING WITHOUT SURGERY MAY PROVE A BOON TO THE ELDERLY, WHO OFTEN ARE POOR SURGICAL CANDIDATES. *(E.)* Waltman, A. C.; Jang, G. C.; Athanasoulis, C. A.; Ring, E. J.; Baum, S. (Harvard Med. Sch., Boston, Mass.). *Geriatrics* 29(3):48-60, 1974.

1959 MULTIFOCAL INTRAHEPATIC ABSCESSES DEMONSTRATED ON PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAM. *(E.)* Jelaso, D. V.; Hirschfield, J. S.; (Clearwater Community Hosp., Fla.). *S. Med. J.* 67(3):310-311, 1974.

1960 SIMULTANEOUS RADIOIMMUNOASSAY FOR CARCINOEMBRYONIC ANTIGEN (CEA) AND ALPHA-FETOPROTEIN (αFP) IN NEOPLASMS OF THE GASTROINTESTINAL TRACT. *(E.)* McIntire, K. R.; Waldmann, T. A.; Go, V. L. W.; Moertel, C. G.; Ravry, M. (Natl. Cancer Inst., Bethesda, Md.). *Ann. Clin. Lab. Sci.* 4(2):104-108, 1974.

1961 FRACTIONATED DOSE ADMINISTRATION SCHEDULE FOR CHOLECYSTOGRAPHY. *(E.)* Fischer, H. W.; Burgener, F. A. (Univ. Rochester Sch. Med., New York). *Invest. Radiol.* 9(1):24-31, 1974.

1962 ASSESSMENT OF FECAL INCONTINENCE BY MANOMETRIC AND RADIOLOGICAL TECHNIQUES. *(E.)* Haberkorn, S.; Chrispin, A.; Nixon, H. H. (Hosp. Sick Children, London, England). *J. Pediatr. Surg.* 9(1):43-47, 1974.

1963 HEMORRHAGIC DUODENITIS: ENDOSCOPIC STUDY. *(E.)* Mann, N. S. (VA Hosp., Topeka, Kan.). *Am. J. Med. Sci.* 266(6):437-439, 1973.

1964 ROUTINE OPERATIVE CHOLANGIOGRAPHY: IS IT REALLY WORTHWHILE? *(E.)* Lewis, Jr., C. E.; McDougal, B.; Peter, E. T. (Univ. New Mexico, Sch. Med., Albuquerque, N.M.). *Am. Surg.* 40(3):139-144, 1974.

1965 DETECTION METHODS FOR STUDY OF THE STABILITY OF HEPATITIS B ANTIGEN ON SURFACES. *(E.)* Favero, M. S.; Bond, W. W.; Petersen, N. J.; Berquist, K. R.; Maynard, J. E. (Bureau Epidemiol., Ctr. Dis. Control., Phoenix, Arizona). *J. Infect. Dis.* 129(2):210-212, 1974.

1966 COMPARISON OF THE PAFS FIXATIVE AND THE POLYVINYL ALCOHOL FIXATIVE METHODS IN THE DIAGNOSIS OF INTESTINAL PROTOZOA AND HELMINTHS. *(Sp.)* Sagua, H.; Subiabre, V.; Torres, P.; Puga, S.; Arias, B. (Dept. Microbiol., Univ. Chile, Santiago). *Bol. Chil. Parasitol.* 28(3-4):58-60, 1973.

1967 INTRAOPERATIVE ENDOSCOPIC EVALUATION OF THE BILE DUCTS. *(E.)* Ottinger, L. W.; Warshaw, A. L.; Bartlett, M. K. (Massachusetts Gen. Hosp., Boston, Mass.). *Am. J. Surg.* 127(4):465-468, 1974.

1968 ENDOSCOPIC CANNULATION OF THE PAPILLA OF VATER. *(E.)* Gaisford, W. D. (Latter-Day Saints Hosp., Salt Lake City, Utah). *Arch. Surg.* 108(4):519-525, 1974.

1969 NORMAL AND PATHOLOGICAL PARAMETERS OF THE LIVER AS MEASURED ON THE SCANNOGRAM. *(E.)* Horn, Y.; Walach, N.; Reich, E.; Hochman, A. (Hadassah Univ. Hosp., Jerusalem). *Nucl. Med.* 12(4):300-308, 1974.

1970 DIAGNOSTIC TECHNIQUES IN GASTROINTESTINAL CANCER. *(E.)* Sherlock, P.; Winawer, S. J. (Mem. Sloan-Kettering Cancer Ctr., New York, N.Y.). *Clin. Bull.* 3(4):127-133, 1973.

1971 DIAGNOSTIC ASPECTS OF SALIVARY GLAND DISORDERS. *(E.)* Diamant, H.; Ericson, S.; Wiberg, A. (Dept. Otophinolaryncol., Univ. Umea, Sweden). *Ann. Clin. Res.* 5(6):357-364, 1973.

1972 BIOPSY OF THE SMALL INTESTINE WITH THE CROSBY-KUGLER CAPSULE: EXPERIENCE IN 3,866 PERORAL BIOPSIES IN CHILDREN AND ADULTS. *(E.)* Greene, H. L.; Rosensweig, N. S.; Lufkin, E. G.; Hagler, L.; Gozansky, D.; Taunton, O. D.; Herman, R. H. (Fitzsimons Army Med. Ctr., Denver, Col.). *Am. J. Dig. Dis.* 19(3):189-198, 1974.

1973 IMMUNOLOGIC TESTS FOR THE DETECTION OF GASTROINTESTINAL CANCERS: STATUS REPORT ON CARCINOEMBRYONIC ANTIGEN (CEA) AND ALPHA-FETOPROTEIN (AFP). *(E.)* Groover, J. R.; Rogers, A. I. (Univ. Miami Sch. Med., Fla.). *S. Med. J.* 66(11):1218-1221, 1973.

1974 THE RIGHT ANGLE UPPER GASTROINTESTINAL SERIES IN THE DIAGNOSIS AND STAGING OF NEUROBLASTOMA. *(E.)* Sorabella, P.; Berdon, W. E.; Baker, D. H. (Babies Hosp., New York, N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 120(3):573-582, 1974.

1975 ENDOSCOPIC EXPERIENCE IN 100 CONSECUTIVE CASES WITH THE OLYMPUS GIF ENDOSCOPE. *(E.)* Papp, J. P. (Blodgett Mem. Hosp., Grand Rapids, Mich. *Am. J. Gastroenterol.* 60(5):466-472, 1973.

1976 ENDOSCOPIC OBSERVATIONS OF GASTRIC VARICES. *(E.)* Okuda, K.; Yasumoto, M.; Goto, A.; Kunisaki, T. (Kurume Univ. Sch. Med., Japan). *Am. J. Gastroenterol.* 60(4):357-365, 1973.

1977 COMPARATIVE STUDY OF TWO DIRECT RADIOIMMUNOASSAY METHODS FOR CARCINOEMBRYONIC ANTIGEN. *(Fr.)* Bali, J. P.; Fournajoux, J.; Sebah, H.; Balmes, J. L.; Marignan, R. (Fac. Pharm., Montpellier, France). *Biol. Gastroenrerol. (Paris)* 6(11):297-306, 1973.

1978 FIBERSCOPIC EXAMINATION OF COLO-RECTAL DISEASES. *(E.)* Koyama, Y. (Natl. Cancer Ctr. Hosp., Tokyo, Japan). *Am. J. Proctol.* 25(2):51-59, 1974.

1979 THE VALUE OF COLONOSCOPY, BIOPSY AND COLONOSCOPIC POLYPECTOMY IN THE DIAGNOSIS AND TREATMENT OF COLONIC POLYPS. *(E.)* Muto, T.; Matsumura, T.; Tomiyama, J.; Hara, K.; Tsuchiya, S.; Williams, C.; Yamashiro, M.; Kanazawa, K.; Ikenaga, T. (Fac. Med., Tokyo Univ., Japan). *Am. J. Proctol.* 25(2):45-50, 1974.

1980 ENDOSCOPIC STUDIES OF COLON POLYPS AND POLYPOSIS. *(E.)* Matsunaga, F.; Tajima, T. (Hirosaki Univ. Sch. Med., Japan). *Am. J. Proctol.* 25(2):41-44, 1974.

1981 THE EFFECT OF POSTURE ON THE MEASUREMENT OF OESOPHAGEAL PRESSURE IN THE CURARIZED SUBJECT. *(E.)* Wildsmith, J. A. W. (Dept. Anaesthetics, Univ. Edinburgh, Scotland). *Br. J. Anaesth.* 45(12):1198-1200, 1973.

1982 MASS SCREENING FOR COLORECTAL CANCER. *(E.)* Hastings, J. B. (Princeton Med. Ctr., N. J.) *Am. J. Surg.* 127(2):228-233, 1974.

83 THE VALUE OF DETERMINATION OF INTESTINAL
ENZYMES IN FECES IN DISEASES OF THE DIGES-
VE SYSTEM. *(Rus.)* Linevsky, Y. V.; Zorina, E. N.
onetsk Med. Inst., USSR). *Vrach. Delo* 2:73-74,
74.

84 SIGNIFICANCE OF SOME INDICES OF THE LIPID
METABOLISM IN THE DIAGNOSIS OF LIVER CIR-
IOSIS. *(Rus.)* Bychkova, V. I.; Boichenko, E. I.
nepropetrovsk. Med. Inst., USSR). *Vrach. Delo*
):55-61, 1974.

85 DIAGNOSIS AND EFFICIENCY OF TREATMENT
CHRONIC PANCREATITIS IN "POSTCHOLECYSTEC-
MY" SYNDROME. *(Rus.)* Gubergrits, A. Y.; Grebel-
ya, S. L. (Kiev Med. Inst., USSR). *Vrach. Delo*
):61-65, 1974.

86 PROBLEMS ENGENDERED BY A "STANDARD
APPROACH" TO ALL PATIENTS WITH JAUNDICE
BILIARY PAIN. *(E.)* Herman, A. H.; Egdahl, R.
; Williams, Jr., L. F.; Nabseth, D. C.; Wittenburg,
(Boston Univ. Med. Ctr., Mass.). *Am. J. Surg.*
7(4):404-409, 1974.

87 CROHN'S DISEASE: THE IMPORTANCE OF
BIOPSY. *(Ger.)* Classen, M.; Rosch, W.;
rtwich, G.; Fruhmorgen, P.; Stocker, B. (Med.
lin. Polyclin., Univ. Erlangen, Germany). *Munch.
ed. Wochenschr.* 116(5):187-190, 1974.

88 CLINICAL EVALUATION OF THE PANCREATIC
SCINTIGRAPHY AS A SCREENING TEST FOR PAN-
EATIC CARCINOMA. *(Jap.)* Watanabe, K.; Kawa-
ra, K.; Koga, K.; Terashima, H.; Matsuura, K.
ac. Med., Kyushu Univ., Japan). *Jap. J. Cancer
in.* 19(2):110-117, 1973.

89 THE DIAGNOSTIC VALUE OF FUNCTIONAL EXPLORA-
TION WITH S_{35} AND Se_{75} METHIONINE IN
PATOPHATHIES. *(Rum.)* Gligore, V.; Dutu, A.;
kete, T.; Mosora, N.; Nastase, I. M.; Holan, T.;
revenco, V.; Miclutia, M. (2nd Med. Clin., Cluj,
mania). *Med. Interna* 25(2):197-203, 1973.

90 X-RAY DIAGNOSIS OF INFLAMMATORY AND TUMOR-
OUS DISEASES OF THE COLON. *(Ger.)*
iedmann, G. (Inst. Radiol., Univ. Cologne, Ger-
ny). *Leber Magen Darm* 3(3):118-123, 1973.

91 $ALPHA_1$-FETO-SERUM PROTEIN (AFP) IN THE
IMMUNOLOGIC DIAGNOSIS OF PRIMARY HEPATOMA.
um.) Luca, N.; Luca, R.; Potorac, E.; Rafael-
efanescu, I.; Adamescu, P.; Ursea, N.; Paun, R.;
metrescu, O.; Genteseu, V.; Ponea, D. (Med. Clin.,
charest, Rumania). *Med. Interna* 25(8):955-961,
73.

1992 ENDOSCOPIC DIAGNOSTICS OF COLONIC DISEASES. *(Ger.)* Frotz, H.; Gheorgiu, T. (Univ. Med. Clin., Cologne, Germany). *Leber Magen Darm* 3(3):124-130, 1973.

1993 LATEX TEST IN THE DEMONSTRATION OF HEPATITIS-ASSOCIATED ANTIGEN: RELATIONSHIP OF NON-SPECIFIC REACTIONS TO CLINICAL FACTORS. *(E.)* Manthey, K. F.; Kreutz, F. H. (Behringwerke AG, Marburg/Lahn, Germany). *Dtsch. Med. Wochenschr.* 98(44):2070-2075, 1973.

1994 EMERGENCY ARTERIOGRAPHY IN UPPER GASTRO-INTESTINAL BLEEDING. *(Fr.)* Schneider, S.; Jacot, C. (La Chaux-de-Fonds Hosp., France). *Lyon Chir.* 69(6):408-410, 1973.

1995 THE VALUE OF INDIRECT PORTOGRAPHY IN SURGICAL TREATMENT OF PORTAL HYPERTENSION. *(Ger.)* Schulz, D.; Frommhold, H.; Bucheler, E.; Kaufer, C. (Surg. Clin., Univ. Bonn, Germany). *Dtsch. Med. Wochenschr.* 99(5):201-203, 1974.

1996 OUR EXPERIENCE WITH LIPID-SOLUBLE CONTRAST MEDIUM IN HEPATOGRAPHY. *(Fr.)* Lamarque, J. L.; Senac, J. P.; Bruel, J. M.; de Sars, P.; Boulet, P. (Univ. Hosp. Ctr., Montpellier, France). *Ann. Radiol. (Paris)* 16(11/12):693-707, 1973.

1997 HEPATIC HISTOLOGICAL ENZYMOLOGY: ITS VALUE IN SOME LIVER DISEASES. *(Fr.)* Monges, H.; Laffargue, P.; Chamlian, A.; Andre, L. J.; Remacle, J. P.; Autard, A. M. (no affil.). *J. Med. Lyon* 54(1241):71-73, 1973.

1998 RELATION BETWEEN THE SPECIFICITY OF THE SEROLOGIC TEST FOR PRIMARY LIVER CANCER AND THE SENSITIVITY OF THE METHOD FOR DETECTING ALPHA-FETOPROTEIN IN DIFFERENT AREAS OF THE WORLD. *(Rus.)* Elgort, D. A.; Abelev, G. I.; O'Conor, G. T. (N. F. Gamaleia Inst. Epidemiol. Microbiol., Moscow, USSR). *Vestn. Akad. Med. Naul SSSR* 27(10):69-75, 1972.

1999 VALUE OF PROPHLACTIC EXAMINATIONS OF HIGH RISK GROUPS FOR EARLY DIAGNOSIS OF STOMACH CANCER. *(Rus.)* Berzin, S. A. (Sverdlovsk Regional Oncol. Dispensary, USSR). *Vopr. Onkol.* 19(12):87-90, 1973.

2000 ACCUMULATION OF CONTRAST MEDIUM IN THE LIVER WHEN THE RETROPERITONEAL LYMPHATICS ARE BLOCKED. *(Ger.)* Muller, K. H. G.; Spaich, I. (Katharinen Hosp., Stuttgart, Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 120(1):50-54, 1974.

2001 DISCRETE MUCOSAL CHANGES IN THE COLON: RADIOLOGICAL DIAGNOSIS OF INFLAMMATORY DISEASES OF THE COLON. *(Ger.)* Cen, M.; Frik, W.;

Karhoff, B.; Ariyama, J. (Med. Fac., Rhine-Westphalian Technical Coll., Aachen, Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 120(1):41-50, 1974.

2002 CROSS-REACTIVITY BETWEEN HEAT LABILE ENTEROTOXINS OF VIBRIO CHOLERAE AND ESCHERICHIA COLI IN NEUTRALIZATION TESTS IN RABBIT ILEUM AND SKIN. *(E.)* Holmgren, J.; Soderlind, O.; Wadstrom, T. (Inst. Med. Microbiol., Univ. Goteborg, Sweden). *Acta Pathol. Microbiol. Scand.* [*B*] 81(6):757-762, 1973.

2003 A STUDY ON THE ACTION OF NORADRENALINE ON IONIC CONTENT AND SODIUM, POTASSIUM AND CHLORIDE EFFLUXES IN THE RAT PORTAL VEIN. *(E.)* Wahlstrom, B. A. (Dept. Zoophysiol., Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 89(4):522-530, 1973.

2004 THE GLYCOLIPIDS OF CANINE INTESTINAL MUCOSA, EXTERNAL MUSCLE, AND GASTRIC MUCOSA. *(E.)* McKibbin, J. M.; Lyerly, D. F. (Dept. Biochem., Univ. Alabama, Birmingham). *Ala. J. Med. Sci.* 10(3):299-304, 1973.

2005 A 3α- AND 7α-HYDROXYSTEROID DEHYDROGENASE ASSAY FOR CONJUGATED DIHYDROXY-BILE ACID MIXTURES. *(E.)* Macdonald, I. A.; Williams, C. N.; Mahony, D. E. (Clin. Res. Ctr., Dalhousie Univ., Halifax, Canada). *Anal. Biochem.* 57(1):127-136, 1974.

GASTROINTESTINAL DISEASES

ESOPHAGUS

2037 THE MALLORY-WEISS SYNDROME. *(E.)*

St. John, D. J. B.; Masterton, J. P.; Yeomans, N. D.; Dudley, H. A. F. (Monash Univ. Med. Sch., Melbourne, Australia). *Br. Med. J.* 1(5899):140-143, 1974.

A policy of immediate investigation of patients with hematemesis or melena or both led to the diagnosis of the Mallory-Weiss syndrome in 16 out of 121 patients admitted to a combined medical-surgical unit over 3.5 yr. Endoscopy with a forward-viewing fibreoptic endoscope was performed as the initial investigation on most patients, usually within 8 hr of the time of admission to hospital. The criterion for the diagnosis of Mallory-Weiss syndrome was the finding of single or multiple longitudinal mucosal tears at, or immediately below, the gastro-esophageal junction. irrespective of the presence or absence of a history of vomiting before hematemesis. The mean age was 45 yr. A factor responsible for development of a mucosal tear was identifiable in 10 cases, vomiting or dry-retching preceded hematemesis in 9 and paroxysmal coughing due to acute bronchitis appeared to be responsible in 1. A further 4 patients had had a high consumption of alcohol before the episode of bleeding but they were unable to recall vomiting before the hematemesis. In 12 of the 16 patients, a linear mucosal tear typical of the Mallory-Weiss lesion was identified at esophagogastroscopy performed as the first investigation in hospital with a forward-viewing endoscope. The diagnosis was suspected in 2 more patients when active bleeding was observed at the gastro-esophageal junction, and the diagnosis was confirmed by repeat esophagoscopy 24 hr later in 1 and at laparotomy in the second. Diagnosis of the remaining 2 was made at laparotomy. The severity of blood loss varied greatly. Blood transfusion was not needed in 4 of the 16 patients but, in contrast, continued bleeding and failure of resuscitative measures necessitate laparotomy in 4 others. When surgery is needed because of continued bleeding, correct preoperative diagnosis of the syndrome could greatly reduce the length of the surgical procedure for a condition which can be difficult to identify at laparotomy.

2038 OESOPHAGEAL APOPLEXY. *(E.)*

Smith, G.; Brunnen, P. L.; Gillanders, L. A.; Teo, H. S. (Roy. Infirm., Aberdeen, Scotland). *Lancet* 1(7854):390-392, 1974.

Three cases of spontaneous bleeding into the wall of the lower esophagus with submucosal hematoma formation are described. The 3 cases all occurred in elderly women with some form of dysfunction of the cardia, associated in 2 with the sliding form of hiatus hernia. The third patient had been taking aspirin daily for several years. The presenting symptom was severe and constant pain behind the lower part of the sternum and in the lower part of the posterior chest. For the first patient, esophagoscopy confirmed the radiological findings; the posterior wall of the esophagus bulged forwards from a level of 25 cm downwards. The overlying intact mucosa was purplish and the swelling was fluctuant, consistent with an underlying collection of blood. A plastic stomach tube exerting gentle suction was passed down, and 35-38 cm from the teeth a little fresh blood was aspirated. Thereafter, the tube was passed into the stomach and left there. The patient was fasted and given i.v. fluids and the symptoms gradually subsided over 36 hr. For the second patient, on esophagoscopy, a large piece of liver impacted at about 30 cm was removed. A raised and hemorrhagic ridge about 10 cm long ran down the posterior wall and bulged into the mucous membrane. There was no sign of a complete rupture and the instrument passed easily into a normal stomach. Radiological examination of the third patient showed that there was a left basal pneumonia, while a gastrografin swallow showed hold-up at the cardia due to spasm. There was a submucosal hematoma above this. Conservative treatment with nasogastric aspiration and i.v. feeding continued for a week. In the past there has been a tendency to attribute lower esophageal and cardiac lesions, whether these were mucosal tears or complete ruptures, to excessive retching and vomiting. It has become increasingly clear that an esophageal tear can occur in the absence of vomiting. Thus sudden straining can cause the condition, presumably by suddenly increasing intragastric or intra-esophageal pressure. Severe pain which produces shock immediately after onset is the symptom common to all complete tears. The importance of recognizing this syndrome would appear to be in differentiating it from a complete esophageal tear or from other catastrophes, such as myocardial infarction, acute hemorrhagic pancreatitis and dissection of the aorta. The conservative treatment and good prognosis of esophageal apoplexy emphasize the importance of its identification.

2039 ESOPHAGEAL INTRAMURAL DIVERTICULOSIS: A CLINICAL AND PATHOLOGICAL SURVEY. *(E.)*

Hammon, J. W., Jr.; (Rice, R. P.; Poslethwait, R. W.; Young, W. G., Jr. (Duke Univ. Med. Ctr., Durham, N. C.). *Ann. Thorac. Surg.* 17(3):260-267, 1974.

Case histories are presented of 3 patients (2 men and 1 woman, aged 19-73 yr) with esophageal intramural diverticulosis. In each of these patients, the roentgenogram of the barium-filled esophagus showed multiple tiny outpouchings similar to diverticula along the course of the esophagus; upper esophageal webs or strictures were also present in all patients, and 1 patient had a hiatal hernia. Esophageal motility in 1 patient was normal, but there was a loss of normal motility in the other 2 patients. Biopsies on all 3 patients showed chronic esophagitis with infiltration of the submucosa of the esophagus by round cells and generalized fibrosis of the esophageal wall. The esophageal glands had become impacted with inflammatory material and had consequently become dilated and inflamed. In all patients pathogenic microorganisms were cultured from the interior of the esophagus. Therapy for this condition should be directed at relieving esophageal obstruction and managing reflex by indicated medical or surgical therapy.

40 ESOPHAGEAL MOTILITY IN SYSTEMIC LUPUS
ERYTHEMATOSUS. *(E.)* Ramirez-Mata, M.;
yes, P. A.; Alarcon-Segovia, D.; Garza, R. (Natl.
st. Nutr., Mexico City). *Am. J. Dig. Dis.* 19(2):
2-136, 1974.

ophageal manometric studies made in 50 unselected
tients with systemic lupus erythematosus disclosed
normalities in 16. Absent or abnormally low
ntractions were found at the upper third in 7, at
e lower two-thirds in 3, in the entire esophagus
2, at the lower esophageal sphincter in 2, and
the lower two-thirds plus the lower sphincter in
e other 2. There is no relationship between the
esence of esophageal dysfunction and activity,
ration, or treatment of lupus at the time of the
udy. Esophageal motor disturbances are part of
e spectrum of systemic lupus erythematosus, although
eir presence does not necessarily reflect activity
the disease. Esophageal dysfunction is not
mited to complete aperistalsis but may occur
lectively at various segments of the organ. A
lationship may exist between this segmental involve-
nt and the differences in their muscular components.
us, involvement of the upper third is more apt to
flect striated muscle disturbance such as is found
polymyositis while that which occurs in the lower
o-thirds would indicate an abnormality of function
fecting the smooth muscle as it is seen in pro-
essive systemic sclerosis.

STOMACH

2067 FURTHER STUDIES OF GASTRIC HYPERSECRETION IN CHRONIC RENAL FAILURE. *(E.)* Shepherd, A. M. M.; Stewart, W. K.; Thjodleifsson, B.; Wormsley, K. G. (Dept. Med., Univ. Dundee, Scotland). *Br. Med. J.* 1(5898):96-98, 1974.

The effect of medical treatment was studied in 4 patients with end-stage renal failure who suffered from severe spontaneous gastric hypersecretion, associated with very low levels of intraduodenal pH in 2 cases. Atropine decreased the overnight gastric acid output, but the residual acid secretion and duodenal content of acid remained dangerously high in one of the patients. Secretin inhibited the basal gastric secretion of acid in all cases and converted the pH of the duodenal contents to alkaline. While atropine cannot be used to control the gastric hypersecretion, secretin may prove to be valuable in the therapeutic management of the gastric hypersecretion of patients with chronic renal failure. It seems probable that in some patients with chronic renal failure, ulceration of the duodenum is related to abnormally great concentrations of acid in the duodenum. The abnormal duodenal content of acid is associated with, and its injurious effects are aggravated by, an impaired pancreatic response to the acid. While anticholinergic drugs do not appear to be therapeutically effective in controlling the excessive gastric secretion and duodenal content of acid, there may be a place for secretin in the treatment of these patients, particularly if long-acting preparations of secretin become commercially available.

STOMACH

Peptic Ulcers

118 MEAT EXTRACT-STIMULATED GASTRIC ACID
SECRETION BEFORE AND AFTER PARIETAL CELL
AGOTOMY WITHOUT ANTRUM DRAINAGE AND SELECTIVE GAS-
RIC VAGOTOMY WITH DRAINAGE IN PATIENTS WITH DUODENAL
LCER. *(E.)* Kragellund, E.; Fischer, J. E.;
ielsen, A. (Kommunehosp., Copenhagen, Denmark).
nn. Surg. 179(2):174-178, 1974.

cid response to meat extract was evaluated in 25
uodenal ulcer patients before and after parietal
ell vagotomy (PCV) or selective gastric vagotomy
ith antral drainage (SV + P). The pentapeptide
est was performed by stimulation with 6 μg Peptavlon/
g s.c. before the operation (25 patients) and with
0 μg Peptavlon/kg s.c. after the operation (19 pa-
ients). The insulin test was performed by stimula-
ion with 0.2 I.U./kg i.v. in 12 patients before and
n 22 patients after operation. For the meat extract
est, 3 oxo cubes were dissolved in 200 ml warm water
nd pH adjusted to 7.0. This solution was introduced
nto the stomach via the tube and left in the stomach
or 15 min. The stomach was then emptied by 5 min
spiration, rinsed by 200 ml of water, and emptied
y a further 5 min aspiration. Before operation, all
atients responded to meat extract with a signifi-
antly increased acid secretion. Peak acid output-
eat extract averaged 60% of peak acid output-
entapeptide. There was a significant positive corre-
ation between peak acid output-meat extract and
asting acid secretion, basal acid output, fasting
olume, and peak acid output-pentapeptide. After
peration there was still a significant, but less
ronounced positive correlation between the fasting
olume and peak acid output-meat extract. After
peration, peak acid output-meat extract was significantly but less prounounced correlated positive with peak acid output-pentapeptide. A significant covariation of reduction of peak acid output-meat extract with peak acid output-pentapeptide could be demonstrated only in the 12 insulin-negative patients, while reductions of peak acid output-meat extract was much more pronounced than reductions of peak acid output-pentapeptide in the 7 insulin-positive patients The entire instilled amount of meat extract could be recovered preoperatively. After the operation, this was the case in only 7 patients, all of whom had a parietal cell vagotomy. In the remaining 14 patients, only about half of the instilled amount could be obtained by aspiration. Meat extract acid secretion is nil or sparse in patients with antral denervation after complete truncal vagotomy and pyloroplasty and after SV + P. The significant meat extract stimulation in patients with intact antral innervation after PCV and in patients with incomplete (insulin-positive) truncal vagotomy and pyloroplasty seems to indicate that innervation of the antrum is necessary for the acid response to feeding with meat extract.

2119 SELECTIVE OR TRUNCAL VAGOTOMY? FIVE-YEAR RESULTS OF A DOUBLE-BLIND, RANDOMIZED, CONTROLLED TRIAL. *(E.)* Kennedy, T.; Connell, A. M.; Love, A. H. G.; MacRae, K. D.; Spencer, F. A. (Roy. Victoria Hosp., Belfast, Northern Ireland). *Br. J. Surg.* 60(12):944-948, 1973.

The 5-year results of a double-blind, randomized, controlled trial of selective versus truncal vagotomy, each with pyloroplasty, are reported. Of 100 patients entering the trial, 95 are available for study. There were 4 suspected or proven recurrent ulcers in the truncal group and 1 suspected but no proven recurrence in the selective group. The incidence of episodic diarrhea was significantly less in the selective group; 4 mild and no severe cases compared with 11 mild and 2 severe cases among the truncal vagotomies. There was no severe dumping; mild symptoms were more common in the selective group but not significantly so. Miscellaneous dyspeptic symptoms were a little more common in the truncal group. Each patient was given a clinical grading using a simplification of the Visick grading as follows: 1. No symptoms: a perfect result. 2. Mild symptoms: not troublesome. 3. More severe symptoms: some degree of disability. 4. Severe symptoms: recurrent ulcer, disabling side-effects, or reoperation. Attention was particularly concentrated upon dumping and diarrhea, which were graded + when quite trivial and often not complained of spontaneously, or ++ when more severe and a significant nuisance to the patient. Using the modified Visick grading, there were 2 failures in the selective group (grades 3 and 4) and 6 failures in the truncal group. Weight changes, hemoglobin levels, and calcium levels were similar and satisfactory in each group. It is concluded that selective vagotomy is superior to truncal vagotomy when each is combined with pyloroplasty.

2120 MECHANISM OF STRESS ULCER: INFLUENCE OF HYPOVOLEMIC SHOCK ON ENERGY METABOLISM IN THE GASTRIC MUCOSA. *(E.)* Menguy, R.; Desbaillets, L.; Masters, Y. F. (Univ. of Rochester Sch. Med. Dent., N.Y.). *Gastroenterology* 66(1):46-55, 1974.

The influence of hypovolemic shock on energy metabolism in the gastric mucosa is presented as a mechanism of stress ulcer. The pathogenesis of stress ulceration remains unexplained. In preliminary experiments on rats it was found that nonlethal hemorrhagic shock induced by removing a volume of blood equivalent to 2.0% of body weight caused severe gastric epithelial necrosis within 15 min and gross erosions within 45 min. The application of the "energy-deficit" hypothesis to the explanation of this experimental model of stress ulceration formed the basis of our studies. Experiments were carried out on male Holtzmann rats. Levels of adenosine triphosphate, adenosine diphosphate, and adenosine monophosphate, glucose-1-P, glucose-6-P, lactate, pyruvate, and glycogen in "stop-frozen" tissues (gastric glandular mucosa, liver, and skeletal muscle) were estimated 15, 30, 45, or 60 min after the induction of shock, as described above. Identical tissue sampling was performed in nonbled rats. In another series of experiments, the same estimations were done on these tissues after 30 and 60 sec of complete, warm ischemia. This degree of hypovolemia caused within 15 min a 75% drop in adenosine triphosphate-fueled energy in gastric mucosal tissue. Liver tissue was much less severely affected in this regard, and muscle not at all. The differences among these three tissues with respect to the influence of hypovolemia on energy were similar in completely ischemic tissues. The data suggest that the extraordinary vulnerability of gastric mucosal energy metabolism to shock-induced ischemia results from this tissue's lack of glycogen (not described previously) and its relative inability to utilize anaerobic glycolysis as an alternate sourc of energy. It is proposed that a profound decrease in energy metabolism in the gastric mucosa is the cau of the rapid cellular necrosis occurring in this tissue during hypovolemic shock.

2121 GASTRIC ULCERS ASSOCIATED WITH DUODENAL ULCERS: 17 CASES. *(Fr.)* Simler, M. (Univ. Hosp. Ctr., Strasbourg, France). *J. Med. Strasbourg* 4(4):289-298, 1973.

Of 540 peptic ulcers observed in a 6-yr period, 17 (3.1%) were gastric ulcers associated with duodenal ulcers. These combined ulcers accounted for 4.7% of all duodenal ulcers and 9.3% of all gastric ulcers diagnosed. The duodenal ulcer developed first in 12 patients and the gastric ulcer, in 2 patients. The second ulcer developed 1-16 yr after the first. In 16 of these 17 patients the gastric ulcer was located in the lesser curvature. Three patients had 2 gastric ulcers each and another had ulcers in the duodenum, stomach, and esophageal cardia. Of the 8 patients who underwent surgery or autopsy, 4 had an active gastric ulcer and a healed duodenal ulcer and 4 had active gastric and duodenal ulcers. Gastric acid secretion, studied in 11 patients, was increased in 6, normal in 2, and decreased in 3. Biopsies and endoscopic examinations, performed on 7 of these patients, showed atrophic gastritis with no evidence of stasis or retention in all 7, pyloric stenosis in only 1, and bile reflux from the duodenum in 5. Complications included 4 severe hemorrhages from the gastric ulcer and 2 duodenal perforations. Four patients died. These included 2 who died of nonulcer-related bleeding (1 from a neoplasm of the colon and 1 from rupture of esophageal varices complicating cirrhosis and liver cancer) and 2 who died of bleedi gastric ulcers and duodenal perforation. Although these findings are not conclusive, they suggest that the duodenal ulcer generally develops first and the gastric ulcer results from bile refluxing into the stomach from the duodenum rather than from pyloric stenosis.

2122 EFFECT OF TRUNCAL VAGOTOMY WITH PYLOROPLASTY OR WITH ANTRECTOMY ON FOOD-STIMULATE GASTRIN VALUES IN PATIENTS WITH DUODENAL ULCER. *(E.* Becker, H. D.; Reeder, D. D.; Thompson, J. C. (Univ. Texas Med. Br., Galveston). *Surgery* 74(4):580-586, 1973.

The effect of vagotomy with pyloroplasty or vagotomy with antrectomy on the serum gastrin response to a meal has been studied in 17 patients (5 females and 12 males, aged 29-65 yr) with duodenal ulcer. The mean fasting gastrin value among patients was 129 pg/ml which differed significantly from the 84 pg/ml value for the 10 control subjects. After a standard meal, gastrin rose to 189 pg/ml in patients and to 122 pg/ml in controls. Basal gastrin increased from a preoperative value of 130 to 167 pg/ml 3 to 6 months postoperatively in the 10 vagotomy with pyloro plasty patients. After a meal, gastrin increased to 198 pg/ml preoperatively and to 268 pg/ml postoperatively. In the 7 vagotomy with antrectomy patients o significant change in basal or food-stimulated gas-rin values occurred. After vagotomy with pyloroplasty r vagotomy with antrectomy, basal and pentagastrin-timulated acid output was diminished about 70%. ince antrectomy caused no significant change in ither basal or postprandial gastrin values, it ap-ears that there are important extra-antral sources f gastrin and this gastrin can be released into the irculation by food. The results of this study support he suggestion that duodenal ulcer patients may have defect in the normal feedback mechanism for inhibi-ion of gastrin release in the presence of increased ates of acid secretion.

123 THE GASTRIC EMPTYING AND SMALL INTESTINAL TRANSIT AFTER HIGHLY SELECTIVE VAGOTOMY ITHOUT DRAINAGE AND SELECTIVE VAGOTOMY WITH PYLORO-LASTY. *(E.)* Madsen, P.; Kronborg, O.; Feldt-asmussen, K. (Bispebjerg Hosp., Copenhagen, Denmark). *cand. J. Gastroenterol.* 8(6):541-543, 1973.

uodenal ulcer patients (54) were treated with either ighly selective vagotomy without drainage (27) or elective vagotomy and pyloroplasty (27). The pa-ients were examined 6 months later by a nutritional ontrast medium. The gastric emptying time and small ntestinal transit time were shorter after selective agotomy and pyloroplasty than after highly selective agotomy. Fast gastric emptying and intestinal pas-age and fluid diffusion into the small intestine ere more frequent in patients with provoked dumping. ontrast filling of the whole colon was seen in pa-ients with provoked diarrhea. Provoked dumping and iarrhea did not occur after highly selective vago-omy. A preserved antrum innervation and pyloric phincter seem to secure a nearly normal gastric eservoir function. Results of this study also sug-est that rapid gastrointestinal passage is important n the pathogenesis of postvagotomy diarrhea.

124 HISTOPATHOLOGY AND PATHOGENESIS OF BEHAVIORALLY INDUCED GASTRIC LESIONS IN RATS. *E.)* Kristt, D. A.; Freimark, S. J. (New York Univ.-ellevue Med. Ctr., New York). *Am. J. Pathol.* 3(2):411-424, 1973.

he development of behaviorally induced acute gastric tress ulcers was studied in Sprague-Dawley, Holtz-an strain, rats. Rats were first trained to press bar for food. During either 19 or 29 consecutive ays of testing they continued to work for food but ere also stressed by mild foot shock, as this treat-ent is ulcerogenic, though otherwise not physically raumatic. Gastric lesions fell into 2 histologic lasses: an acute ulcerative-hemorrhagic process ith several different manifestations and a focal lear cell metaplasia of the gastric pit epithelium. egarding the pathogenesis of hemorrhagic-ulcerative esions, the ulcers have the appearance of mucusal nfarcts. At times simple hemorrhage was observed nly above or only below the muscularis mucosa, sug-esting that the hemorrhage originated in the plexus f blood vessels in the muscularis mucosa and was he likely result of either thromboembolic occlusion, asoconstriction or extrinsic compression of these essels. Fibrin microthrombi or microemboli were ot apparent. It is suggested that stress induced sustained constriction of the blood vessels of the muscularis mucosa, resulting in focal mucosal infarction. The gastric pit metaplasia may reflect a response to a stress-induced impairment of the protective mucous coat. In addition, preliminary data suggest that ulceration and healing occur continuously throughout the test period, so that no ulcer progressed to perforation.

2125 RELATIONSHIP BETWEEN SERUM GASTRIN CONCENTRATIONS AND GASTRIC ACID SECRETION IN DUODENAL ULCER PATIENTS BEFORE AND AFTER SELECTIVE AND HIGHLY SELECTIVE VAGOTOMY. *(E.)* Kronborg, O.; Stadil, F.; Rehfeld, J.; Christiansen, P. M. (Bispebjerg Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 8(6):491-496, 1973.

Serum gastrin concentrations were measured by radioimmunoassay and studied in relation to gastric acid secretion during insulin tests (0.2 IU/kg, i.v.) performed on duodenal ulcer patients. Studies were conducted both before and about 10 days after operation on 17 patients treated with selective vagotomy and pyloroplasty and in 17 others treated with highly selective vagotomy without drainage. Augmented histamine tests were performed pre- and postoperatively and the results were related to serum gastrin concentrations. The gastrin and acid response to hypoglycemia were positively related before operation, but not after the 2 vagotomies; the acid response had been reduced and the gastrin response remained unchanged. No relation was found between serum gastrin concentrations and histamine-activated acid secretion, either pre- or postoperatively.

2126 INHIBITION BY SECRETIN OF THE GASTRIC ACID RESPONSES TO MEALS AND TO PENTAGASTRIN IN DUODENAL ULCER PATIENTS. *(E.)* Konturek, S. J.; Biernat, J.; Grzelec, T. (Med. Acad., Cracow, Poland). *Gut* 14(11):842-846, 1973.

The inhibitory effects of i.v. secretin on the gastric acid responses to a meal and to pentagastrin were studied in 7 duodenal ulcer patients (aged 22-46 yr). A test meal of 10% peptone adjusted to pH 5.0 was introduced into the stomach and the Fordtran and Walsh method was used to measure the gastric acid output by monitoring the rate at which a solution of 0.3 M sodium bicarbonate had to be added to keep the pH of the gastric content constant at the value of 5.0. A constant dose of secretin (1 U/kg/hr) significantly depressed the serum gastrin response to a meal and inhibited acid secretion by about 70%. Secretin inhibited the acid response induced by pentagastrin (2 μg/kg/hr) by about 60% and simultaneously provoked a pancreatic bicarbonate output sufficient to neutralize about 60% of the gastric acid output to pentagastrin. It was concluded that secretin is a strong inhibitor of gastric secretion induced by a meal and by pentagastrin in duodenal ulcer patients.

2127 PROPRANOLOL AND SERUM GASTRIN IN POSTVAGOTOMY INSULIN TESTS. *(E.)* Hall, W. H.; Durkin, M. G.; Read, R. C. (Little Rock VA Hosp., Oklahoma City, Okla.). *Digestion* 9(4):325-331, 1973.

Serum gastrin was measured by radioimmunoassay during postvagotomy insulin tests in 33 patients. In 11, the study was preceded by propranolol 20 mg, p.o. Gastric acid output was lower in the group pretreated with propranolol. There was no difference in serum gastrin between Hollander positive versus Hollander negative insulin tests. Propranolol affects insulin-stimulated gastric secretion in ways other than by affecting total serum gastrin. These observations reinforce the position that if positive versus negative interpretations of acid secretion in the insulin test have any significance for vagal integrity at all, Hollander's criteria are considerably too sensitive. Although acid secretion stimulated by insulin was reduced after propranolol, serum gastrin was unchanged. Thus, the depressing effect of partial β-adrenergic blockade on insulin-stimulated gastric acid secretion did not appear to be mediated through any effect on serum gastrin concentration.

2128 BILE REFLUX IN GASTRIC ULCER: THE EFFECT OF SMOKING, METOCLORPRAMIDE AND CARBENOXOLONE SODIUM.

(E.) Dippy, J. E.; Rhodes, J.; Cross, S. (Univ. Hosp. Wales, Cardiff). *Curr. Med. Res. Opinion* 1(9):569-575, 1973.

The degree of bile reflux into the stomach was examined during a standard test meal in 26 patients with gastric ulcer. The test meal was repeated within 7 days in 10 patients who smoked during the second test; the degree of reflux increased considerably in 6. In a further 10 patients the test was repeated 15 min after an oral dose of metoclopramide; there was no change in the degree of reflux. In 6 other patients the effect of a single dose and also of 1 week's treatment with carbenoxolone was examined. There was no change in the degree of bile reflux observed in either the second or third tests. Although oral metoclopramide and carbenoxolone appeared to have no effect on bile reflux into the stomach, smoking increased reflux considerably in 6 of 10 patients. The significance of these findings is discussed with reference to therapy in gastric ulcer. It may be that patients who continue to smoke delay healing of gastric ulcer by repeatedly provoking excessive bile reflux into the stomach.

2129 TRANSMITTAL OF RESTRAINT-INDUCED GASTRIC ULCERS BY PARABIOSIS IN RATS.

(E.) Tran, T. A.; Gregg, R. V. (Univ. Louisville Sch. Med., Ky.). *Gastroenterology* 66(1):63-68, 1974.

The transmittal of restraint-induced gastric ulcers by parabiosis was studied in 62 genetically similar female rats of the ARS Fischer 344 strain, with an average weight of 180 grams. One rat of a parabiosed pair was restrained for 28 or 30 hr on a mobile cart which its unrestrained mate was free to pull about. All restrained animals showed gastric ulceration, and 15 of 17 unrestrained mates also developed gastric ulceration. The results show that the factor or factors producing restraint ulcers in the restrained member of a parabiotic pair of rats can be transmitted to the unrestrained mate. This induction of ulcers implicates a humoral factor in the etiology of stress-induced gastric ulcers.

2130 GASTRIN RESPONSE TO INSULIN AFTER SELECTIVE HIGHLY SELECTIVE, AND TRUNCAL VAGOTOMY.

(E.) Stadil, F.; Rehfeld, J. F. (Rigshosp., Copenhagen, Denmark). *Gastroenterology* 66(1):7-15, 1974.

The role played by the vagus in release of immunoreactive gastrin was studied in duodenal ulcer patients before and after selective, highly selective, and truncal vagotomy. Postoperatively, gastrin concentrations before aspiration of the stomach were fro 1 1/2 to 2 times higher than preoperative concentrations. During continuous aspiration, gastrin concentrations decreased significantly after all 3 operations. Basal gastrin concentrations, as measured during aspiration, increased significantly after highly selective vagotomy (17 patients) from 24 ± 1.8 to 35 ± 4.4 pmoles/liter of serum (53 to 77 pg/ml), and truncal vagotomy (18 patients) from 28 ± 3.1 to 43 ± 4.2 (62 to 95 pg/ml), but not after selective gastric vagotomy (17 patients) from 28 ± 2.7 to 33 ± 2.4 (62 to 73 pg/ml). The mean increase after truncal vagotomy was significantly higher than after selective vagotomy, suggesting that extragastric vagal branches, by some action, suppress gastrin release. Before and after the operations, gastrin concentrations in serum increased significantly after intravenous injection of 0.2 IU of insulin/kg. The increase lasted more than 1 1/2 hr and was only moderately affected by the 3 operations. A persisten gastrin response to insulin was also found in 11 patients with truncal vagotomy and anacid specimens of gastric juice during hypoglycemia, when measured with three different antisera. The findings indicate that the release of immunoreactive gastrin by hypoglycemia does not depend solely on the vagus.

2131 ALTERED PANCREATIC AND BILIARY FUNCTION AFTER VAGOTOMY AND PYLOROPLASTY.

(E.) Malagelada, J. R.; Go, V. L. W.; Summerskill, W. H. J. (Mayo Clin., Rochester, Minn.). *Gastroenterology* 66(1):22-27, 1974.

Changes in pancreatic enzyme section and gallbladder contraction occurring after vagotomy and pyloroplasty in 12 patients were investigated and compared with findings from 17 healthy male volunteers and 9 patients with uncomplicated duodenal ulcer. Total lipase and bile acid outputs were quantified, using duodenal perfusion, under basal conditions and in response to both endogenous cholecystokinin-pancreozymin (CCK-PZ) (released by intraduodenal perfusion of essential amino acids) and to exogenous (porcine) CCK-PZ given by vein. After vagotomy and pyloroplast basal pancreatic enzyme outputs were reduced, as were responses to both intraduodenal essential amino acid perfusion and lower doses of intravenous CCK-PZ, but the response to maximal doses of intravenous CCK-PZ was normal. By contrast, gallbladder contraction occurred at a lower dose of intravenous CCK-PZ than in healthy subjects or in patients with duodenal ulcer, although the response to intraduodenal essential amino acids was normal. The results suggest that vagal impulses contribute to pancreatic enzyme secretion in the interdigestive periods; and after vagotomy and pyloroplasty, sensitivity of the pancreas to CCK-PZ decreases and that of the gallbladder increases.

32 GASTRIC ACID RESPONSE TO SHAM FEEDING IN THE DUODENAL ULCER PATIENT. *(E.)* Knutson, ; Olbe, L. (Sahlgrenska Hosp., Stockholm, Sweden). *and. J. Gastroenterol.* 8(6):513-522, 1973.

sham feeding technique was developed for patients erated on for peptic ulcer. The technique permits udy of the gastric acid secretory response to ysiological vagal activation. Patients may eat d swallow an ordinary meal, which is prevented om reaching the stomach by means of a rubber tube, mporarily inserted into the distal part of the ophagus via a gastrostomy. An analysis of the w sham feeding method suggests that it truly flects the acid response to physiological vagal tivation, and that the acid secretory response is producible. Sham feeding for 15 min produced a ar maximal sham feeding acid response. In 18 odenal ulcer patients with intact antrum 15 min am feeding produced an increased gastric acid cretion, usually lasting for more than 2 hr, with mean peak response amounting to 11.7 mEq/30 min 5% of the mean peak acid response to pentagastrin, µg/hr, i.v. for 45 min followed by 300 µg/hr for -60 min, or Histalog, 2 mg/kg, s.c.). No correlaon was found between the peak acid sham feeding sponses and the peak acid responses to pentagasin or Histalog.

33 DOUBLE-BLIND TRIAL OF DEGLYCYRRHIZINATED LIQUORICE IN GASTRIC ULCER. *(E.)* Engqvist, ; Von Feilitzen, F.; Pyk, E.; Reichard, H. (Southn Hosp., Stockholm, Sweden). *Gut* 14(9):711-715, 73.

trial with a double-blind, cross-over design was ed to investigate the reported beneficial effect deglycyrrhizinated liquorice in gastric ulcer. tients were treated during 2 consecutive periods 4 weeks each with either liquorice extract during e first period and placebo during the second or acebo during the first and liquorice during the cond. Only patients with chronic ulcer disease re studied. The site of ulceration included prelotic, canalis, angulus, and corpus. The dosage the liquorice extract was 760 mg, 3 times/day. ring the first period 38 patients with 47 ulcers the ventricle were studied. During the second riod 30 patients with 36 ulcers took part in the ial. The patients' sex, age, site of ulcer in e ventricle, and ulcer size in the groups treated th liquorice and placebo during periods I and II re similar. Nor could any difference be shown tween the groups treated with liquorice and placebo th respect to heredity, duration of ulcer disease, cohol consumption, smoking, or use of drugs. There s no tendency to quicker healing in either group regards change of ulcer area or complete healing. all ulcers healed more quickly than big ones. cers at the angulus healed very poorly. No side fects of treatment were observed. This study did t demonstrate any healing effect of the liquorice tract on gastric ulcer.

34 INHIBITION OF GASTRIC PLASMIN ACTIVITY BY EPSILON-AMINOCAPROIC ACID. *(E.)* Thomson, J. M.; Turner, L.; Poller, L. (Univ. Hosp., South Manchester, England). *Ann. R. Coll. Surg. Engl.* 53(6):340-347, 1973.

Preoperative administration of the antifibrinolytic drug epsilon-aminocaproic acid (3 doses of 0.1 g/kg, p.o.) prevented the release of plasmin activity following digital compression of the stomach at operation in 13 of 14 patients with duodenal ulceration. In a paralleled control series all of 15 duodenal ulcer patients not given epsilon-aminocaproic acid showed marked increase in fibrinolysis, as evidenced by progressive shortening of the lysis times in the serial venous specimens from the first to the third peripheral sample. Areas of lysis indicating plasmin activity were seen in the gastric and third peripheral venous samples in each patient. In 13 of these 15 the activity was also present in the second peripheral venous samples. In addition to the gastric venous blood, the second and third peripheral venous samples showed increased fibrin/fibrinogen breakdown product levels. The epsilon-aminocaproic acid treated series, apart from 1 patient with pyloric stenosis, showed increased plasminogen activator only, presumably due to stress, anesthesia, and no increase of fibrin/fibrinogen breakdown products. Antifibrinolytic drugs may become an important new factor in the management of bleeding from acute gastric erosions, through inhibition of gastric plasmin activity.

SMALL INTESTINE

2146 THE INTESTINAL COMPLICATIONS OF RADIOTHERAPY. *(E.)* Wellwood, J. M.; Jackson, B. T. (St. Thomas's Hosp., London, England). *Br. J. Surg.* 60(10):814-818, 1973.

Clinical findings are reported for 38 patients (26 women, 12 men; aged 39-76 yr) with intestinal complications after radiotherapy for malignant disease. Large-bowel complications occurred in 25 patients and included proctocolitis (18), colorectal stricture (13), anal stricture (4), rectal ulcer (7), spontaneous necrosis (3), and fistula (3). Small-bowel complications developed in 21 patients and consisted of stricture (11), malabsorption (9), spontaneous necrosis (6), fistula (2), and impaired healing (6). Intestinal complications were commonly progressive and led to the death of 14 patients (37%). Of these patients, 9 had no sign of recurrent tumor. Spontaneous necrosis of the irradiated bowel or necrosis of an intestinal anastomosis accounted for 11 of the deaths. Only 3 patients became completely asymptomatic after treatment of their bowel disease. Apparently localized radiation lesions in the small bowel were associated with severe malabsorption of fat, vitamin B_{12}, and calcium. Radiographs showed striking mucosal changes in the small bowel; nodular filling defects resembling small-bowel metastases were also seen. A combined radiotherapy/surgical follow-up clinic is advocated.

2147 SMALL-INTESTINAL INJURY IN WOMEN WHO HAVE HAD PELVIC RADIOTHERAPY. *(E.)* Newman, A.; Katsaris, J.; Blendis, L. M.; Charlesworth, M.; Walter, L. H. (Central Middlesex Hosp., London, England). *Lancet* (7844):1471-1473, 1973.

Small-bowel injury from pelvic irradiation was studied in 17 women who had received intracavitary radium, external x-rays, and telecobalt radiotherapy, alone or in combination. Subjects with evidence of recurrent malignancy were excluded from the study. Of the 17 women, 12 had a permanent increase in stool frequency. The presence and severity of this alteration did not depend on the nature of the lesion treated, the type of radiation received, the dose administered, or whether or not surgery was performed. Sixteen subjects had abnormal cholyglycine-1-(^{14}C) breath tests, including all 12 with symptoms of increased bowel frequency. While 8 of 11 small-bowel x-rays were abnormal, only 1 of 13 rectal biopsies showed inflammatory changes and only 1 showed vascular thickening suggestive of radiation injury. No subject had blood in her stools. It is concluded that alteration in stool habit and interruption of enterohepatic circulation, as indicated by abnormal breath tests, are caused by radiation injury to the small bowel. Such injury is an almost invariable accompaniment to all forms of radiotherapy.

2148 RETROANASTOMOTIC HERNIA. *(E.)* Johnson, J. M.; Wood, M.; Lawson, J.; Hale, H. W., Jr. (Maricopa County Gen. Hosp., Phoenix, Ariz.). *Arch. Surg.* 108(3):363-365, 1974.

Since 1897, 175 cases of retroanastomotic herniations have been reported. Over 30% of the patients who underwent laparotomy died, while all of those who were not surgically treated died. The successful management of 3 additional patients, 2 with efferent-loop herniation and 1 with afferent-loop herniation, is reported. The latter patient, a 49-yr-old man, may be the only one who has survived gangrene of the duodenum secondary to an obstruction with strangulation of the afferent loop. The cause of internal herniation following gastroenterostomy is probably dependent on 3 variables: the length of the afferent limb; retrocolic or antecolic placement; and isoperistaltic or antiperistaltic anastomosis. No gastrointestinal anastomosis is free from potential herniation unless the space is closed by sutures. The majority of herniations show symptoms within the 1st month of surgery, but the symptoms may appear as long as 13 years later. Closure of the internal hernial ring at the time of the initial gastric operation prevents the formation of retroanastomotic hernia.

49 ACUTE INTESTINAL OBSTRUCTION SECONDARY TO
VASCULAR COMPRESSION OF THE DUODENUM.
.) Paul, J. G.; Eggleston, F. C.; Singh, C. M.
hristian Med. Coll., Ludhiana, Punjab, India).
. *J. Surg.* 12(4):658-660, 1973.

ve cases of acute upper intestinal obstruction
used by mesenteric vascular compression of the
odenum are presented. None of the 5 patients (4
ys, 1 girl; aged 16-18 yr) had a history of
strointestinal complaints. All had copius bilious
miting and all were thin; only 1 did not present
th marked dehydration or abdominal distension.
boratory findings were unremarkable, except for
blood urea of 180 mg/100 ml (1 patient), white
ood cell count of 22,000/m cu m (1), mild acidosis
th a base excess of -6.9 mEq/liter (1), and
tabolic alkalosis with a base excess of +10.0
). In 1 patient, patchy gangrene of the stomach
dicated the severity of the obstruction. In other
ses, laparatomy showed the stomach and duodenum
re distended to the crossing of the superior
senteric artery. All patients were successfully
eated by duodenjejunostomy. Mesenteric vascular
mpression in these patients was apparently associa-
d with thiness and a known bulky diet, which may
ve resulted in undue traction on the mesentery.

50 MECKEL'S DIVERTICULUM: UNUSUAL PREOPERA-
TIVE PRESENTATIONS. *(E.)* Martinez, R.;
lbiger, M. L. (Tampa Gen. Hosp., Fla.). *South.*
d. J. 67(4):501-502, 1974.

o unusual preoperative radiologic diagnoses involv-
g Meckel's diverticula are presented: Meckel's
verticulum calculus and Meckel's diverticulum
ading an ileocolic intussusception. Meckel's di-
rticulum leading the intussusception was found in
11-month-old female infant who presented clini-
l signs of small bowel obstruction and rectal
eeding. Roentgenogram clearly demonstrated an
eocolic intussusception led by a diverticulum.
e intussusception could not be successfully re-
ced, and the patient was taken to surgery. Fol-
wing reduction of the intussusception and resection
the diverticulum and a portion of small bowel,
e patient had an uneventful postoperative recovery.
e second patient, a 9-yr-old boy, was admitted
th rectal bleeding, crampy abdominal pain, and
idence of blood loss anemia. A small bowel series
owed a triangular calcification within a diverti-
lum in the distal ileum, which fluoroscopically
owed evidence of contractility. At operation, a
ckel's diverticulum containing gastric mucosa,
localized ulceration, and a triangular calculus
s found. The patient had an uneventful recovery.

SMALL INTESTINE

Malabsorption

2178 TUMORS AND EOSINOPHILIC GRANULOMAS OF THE SMALL INTESTINE IN MALABSORPTION. *(Ger.)* Balmer, F.; Stucki, P.; Pedrinis, E.; Halter, F. (Inselspital, Bern, Switzerland). *Schweiz. Med. Wochenschr.* 104(3):78-83, 1974.

Case reports are presented for 6 patients who had malabsorption syndrome associated with benign or malignant tumors of the small intestine. These patients consisted of 4 men and 2 women who were 40-68 yr old when the tumor was diagnosed and who had histories of steatorrhea dating back 2-19 yr. In all cases the diagnosis of malabsorption was based on clinical findings and total or subtotal villous atrophy found in biopsies of the small intestine. Temporary clinical improvement occurred in 4 patients when they were placed on a gluten-free diet. In 4 of the 6 cases the tumor was diag-

sed at emergency laparotomy after spontaneous
rforation of the small intestine resulting from
crotic colliquation of one or more tumors. In
e remaining 2 cases the tumor caused partial ob-
ruction and a radiological filling defect in the
odenum and jejunum, resp. Tumors consisted of
und to polymorphocellular sarcomas (2 cases),
sinophilic granulomas (2 cases) a reticulum cell
rcoma (1 case), and an adenocarcinoma (1 case).
rvival times after surgery ranged from 3 days to
yr. One patient with an eosinophilic granuloma is
ive and well 3 yr after surgery. The long inter-
l from onset of steatorrhea to tumor development
d early villous atrophy suggest that the tumor is
condary to malabsorption. Although changes in
munoglobulins have been suggested as a cause for
e increased incidence of neoplasms in malabsorption,
l of these patients had normal serum immunoglobulin
vels.

Polak, J. M.; Pearse, A. G. E.; Van
orden, S.; Bloom, S. R.; Rossiter, M. A. (Roy.
stgrad. Med. Sch., London, England). *Gut*
(11):870-874, 1973.

munofluorescence (anti-secretin), cytochemical, and
trastructural studies were carried out on jejunal
opsies from 16 children (aged 9 months to 14 yr)
th celiac disease and from 17 children (aged 12
nths to 14 yr) with suspected malabsorption but
rmal jejunal morphology. In 11 of the 16 celiac
tients, immunofluorescence showed generalized
perplasia of endocrine cells and, specifically,
the secretin (S) cells. Most celiac biopsies
d subtotal villous atrophy and 3 showed partial
llous atrophy. Large numbers of argyrophilic
lls were found in 4 celiacs, moderately large
mbers in 6 and a smaller number in a single case.
the 11 celiac cases, 10 showed numerous or very
merous positively stained cells with lead hematoxy-
n. Electron microscopy also revealed large numbers
S cells as well as intermediate, enterochromaffin,
d enteroglucagon cells in both control and celiac
opsies. Further studies, on adult celiacs as well
on children, combined with serum assays may
tablish whether the S cells are abnormally storing
rmone because of inability to release it or be-
use of excess production.

80 THE IMMUNOHISTOCHEMISTRY OF THE INTESTINAL
MUCOSA IN MALABSORPTION SYNDROME IN CHIL-
EN. *(Fr.)* Joe, J. (Hosp. Enfants-Malades, Paris,
ance). *Ann. Gastroenterol. Hepatol. (Paris)*
2):139-147, 1973.

munofluorescence techniques were used to examine
biopsies from the small intestine of 23 children
th celiac disease, 13 biopsies from 11 children
th intolerance to cow's milk, 8 biopsies from
ildren with other gastrointestinal diseases (4
th protein-losing enteropathy, 2 with colitis,
d 2 with idiopathic malabsorption), and 9
opsies from normal controls with no evidence of
labsorption or intestinal lesions. Biopsies were
ken before and after treatment and during challenge
in patients with malabsorption. Serum immunoglobulins (Ig) were also determined. In children with active forms of celiac disease the absolute number of cells secreting IgA and IgM was increased as was the serum IgA level. In untreated patients with intolerance to cow's milk the number of cells secreting IgA and serum IgA levels were increased. In one patient with celiac disease associated with an IgA deficiency there were no cells in the intestinal mucosa which secreted IgA, but the number of cells secreting IgM was significantly increased. In protein-losing enteropathy no changes were found in the relative proportions of IgA-, IgG-, and IgM-secreting cells, but the levels of almost all serum Ig Fractions were decreased. Although these findings suggest that an immunological mechanism is involved in the malabsorption syndrome studied, the relation between immunological abnormalities and intestinal lesions remains unknown.

2181 PLASMA AND URINARY ZINC IN PATIENTS WITH MALABSORPTION SYNDROMES OR HEPATIC CIRRHOSIS. *(E.)* Walker, B. E.; Dawson, J. B.; Kelleher, J.; Losowsky, M. S. (St. James's Hosp., Leeds, England). *Gut* 14(12):943-948, 1973.

Plasma and urinary zinc were measured in 19 pa-patients with malabsorption and 21 patients with hepatic cirrhosis. The results were compared with those of 20 control subjects and 23 patients with a variety of other diseases. The diurnal variation in plasma zinc levels has been confirmed and is of such magnitude that this must be taken into account in comparing results in groups of subjects. Plasma zinc levels, both fasting and after a meal, are significantly lower in patients with cirrhosis (71 and 60 μg/100 ml) and malabsorption (76 and 64 μg/100 ml) than in controls (97 and 81 μg/100 ml). In the patients with cirrhosis or malabsorption similar correlations exist between plasma zinc and plasma albumin, suggesting that the low plasma zinc levels may be at least in part, dependent on the plasma albumin level. Urinary zinc excretion is increased in cirrhosis, but not in malabsorption, indicating that increased urinarly loss is unlikely to explain the low plasma levels.

2182 THE OCCURRENCE OF CYSTIC FIBROSIS AND CELIAC SPRUE WITHIN A SINGLE SIBSHIP. *(E.)* Franklin, J. L.; Asquith, P.; Rosenberg, I. H. (Pritzker Sch. Med., Univ. Chicago, Ill.). *Am. J. Dig. Dis.* 19(2):149-155, 1974.

A family in which cystic fibrosis and celiac sprue occurred within the same sibship is studied and 3 case reports are presented. The Index Case was a 29-yr-old white housewife. Physical examination revealed a thin pale female with a large smooth tongue, slight finger clubbing, and abdominal distention. A peroral jejunal biopsy showed complete loss of normal villous architecture, cuboidal epithelium, and a marked increase in the inflammatory cell infiltration in the lamina propria and epithelial cell layer. The patient was placed on a gluten-free diet and 2 weeks later noted that her bowel movements changed from watery and greasy to solid and reduced in frequency from 5 or 6 to 1 or 2 times each day. Three months after an uneventful pregnancy, the patient was restudied, 15 months after gluten withdrawal. Small bowel biopsy showed partial villous formation, a return to normal columnar epithelium, and a decrease in the inflammatory cell infiltrate. A clinical diagnosis of celiac sprue was suggested on the basis of the clinical hematological and biochemical features including the increased fecal fats, the low D-xylose excretion, the low serum folate associated with a malabsorption of pteroylmonoglutamate and heptaglutamates, and the abnormal X-ray appearances of the small intestine. Case 2 was a 21-yr-old school teacher and female cousin of the index case. She was evaluated becase of a history of celiac disease in childhood. A clinical diagnosis of celiac sprue was made and the diagnosis was confirmed by the appearance of the jejunal biopsy and her response to gluten withdrawal which included an increased feeling of well being, a reduction in stool count, and a return to normal of D-xylose excretion. The 12-yr-old sister of the index case developed respiratory infection at the age of 3 weeks requiring hospitalization. A diagnosis of cystic fibrosis was made. The demonstration of both cystic fibrosis and celiac sprue in the same family is important and means that all cases of malabsorption in a family, although superficially similar, must be separately investigated; it cannot be assumed that all have either celiac disease or fibrocystic disease. Both diseases may occur in the same individual.

2183 THE EFFECT OF GLIADIN PEPTIDES ON RAT-LIVER LYSOSOMES IN RELATION TO THE PATHOGENESIS OF COELIAC DISEASE. *(E.)* Cornell, H. J.; Townley, R. R. W. (Roy. Children's Hosp., Melbourne, Australia). *Clin. Chem. Acta* 49(2):181-188, 1973.

Several fractions of a peptic-tryptic-pancreatic digest of wheat gliadin were evaluated for their effect on rat liver lysosomes in studying the etiology and pathogenesis of celiac disease. On incubation with lysosome suspensions, Fraction 9 caused a greater degree of disruption of the lysosomes than did any other primary fraction of the digest. The activity of Fraction 9 was measurable at concentrations of 10^{-4} M. Peptides remaining after incubation of Fraction 9 with homogenates of duodenal mucosa from 5 children with celiac disease in remission still had an appreciable effect on lysosomal membranes, in contrast to residues obtained from digestion with homogenates from control individuals. It is suggested that the primary abnormality in celiac disease is a deficiency of an intestinal peptidase which allows accumulation of unduly high concentrations of certain gluten peptides in the gut. The present results indicate that the lesion of celiac disease may be due to the direct effect of such peptides on lysosomes, although less idrect or complementary mechanisms of pathogenesis can not be excluded. These results point to peptides present in Sub-fraction 2 of Fraction 9 as the most active to lysosomes. Subfraction 2 contains 3 major groups of peptides; 2 are active to lysosomes.

2184 WHIPPLE'S DISEASE PRESENTING AS PLEUROPERICARDITIS. *(E.)* Pastor, B. M.; Geerken, R. G. (Madigan Gen. Hosp., Tacoma, Wash.). *Am. J. Med.* 55(6):827-831, 1973.

A diagnosis of Whipple's disease was made by peroral jejunal biopsy in a 48 yr old woman with pleuropericarditis of unknown etiology who had been followed for 4 yr prior to the onset of clinical and laboratory signs of malabsorption. Pretreatment immunologic investigations revealed lymphopenia, decreased immunoglobulin G levels, 580 mg/100 ml, with normal immunoglobulin A and M serum levels, and marked impairment of delayed hypersensitivity. Procaine penicillin (1.2 million units) and streptomycin (1.0 mg, i.m.) were given for 10 days. The patient was thereafter maintained on tetracycline (0.5 g twice/day) for 1 yr. Following successful treatment, the total lymphocyte count and serum immunoglobulin G level returned to normal, and there was no demonstrable impairment in delayed hypersensitivity. This latter observation contrasts with recent reports of immunologic investigations in Whipple's disease patients which demonstrated that most continue to manifest significant deficits in delayed hypersensitivity despite successful therapy.

2185 INTOLERANCE OF SMALL AMOUNTS OF LACTOSE BY INDIVIDUALS WITH LOW LACTASE LEVELS. *(E.)* Bedine, M. S.; Bayless, T. M. (Johns Hopkins Univ. Med. Sch., Baltimore, Md.). *Gastroenterology* 65(5):735-743, 1973.

Lactose (3 to 96 g) was fed to 20 subjects with assay-confirmed low lactase levels to determine a threshold level for symptoms of lactase intolerance. Of these 20, 75% had symptoms of flatulence, distention, cramps, loose bowel movements, or diarrhea with 12 g of lactose (equivalent to 8 ounces of milk) or less. With as little as 3 g of lactose, 2 individuals were symptomatic. All 20 subjects were asymptomatic with equivalent amounts of sucrose or a glucose-galactose mixture. Neither the type of symptoms, the specific intestinal lactase levels, nor the presence of the irritable colon syndrome correlated with the threshold level for symptoms. To determine the intraluminal events occurring with small amounts of lactose, 7 low lactase level subjects and 3 control subjects underwent intestinal intubation with aspiration ports in the duodenum, jejunum, and ileum. They received 24, 12, 6 or 3 g of lactose with polyethylene glycol, a nonabsorbable marker, in a solution similar to the electrolyte composition of milk. Subjects with low lactase levels had persistently low polyethylene glycol concentrations in the jejunum and ileum, representing fluid accumulation, as compared with control subjects, in whom high concentrations of polyethylene glycol in the jejunum and ileum represented net absorption. Differences from control subjects were statistically significant in the jejunum and ileum for 24 g and 12 g of lactose and in the jejunum for 6 g of lactose. In addition to the increased fluid load, the concentrations of sodium in the duodenum were higher in low lactase level subjects (mean 64.6

nEq/liter) than in control subjects, and potassium
concentrations in the duodenum were lower (mean 7.1
nEq/liter) than in controls. Thus, there was ob-
jective evidence of fluid and sodium accumulation
in the small bowel with these small lactose loads.
It is presumed that increased speed of transit and
intracolonic fermentation are also significant in
symptom production.

LARGE INTESTINE

193 CARCINOMA OF THE RECTUM IN OLD AGE. *(E.)*
Jensen, H.-E.; Balslev, I.; Fenger, H. J.;
ragelund, E.; Nielsen, J. (Munic. Hosp., Copen-
agen, Denmark). *Acta Chir. Scand.* 139(6):563-
67, 1973.

he results of treatment of 356 patients, aged over
0 yr, with carcinoma of the rectum are discussed.
f the 356 patients, 48% were not operated, or under-
ent only laparotomy, and some relieving or local
rocedure. The remaining 185 patients (52%)
nderwent low anterior resection, perineo-abdominal
xtirpation in 2 sessions, or adbomino perineal ex-
irpation in 1 section. All resections and 50% of
he extirpations were performed after bowel steriliza-
ion. Primary operative mortality in the 185
atients undergoing resection or extirpation was
1%. In 82 patients undergoing laparotomy with
r without some palliative procedure, mortality was
2%. Of all the 356 patients, 22% died during ad-
ission, and 55% within the first year. Of the
3 patients not operated, or in whom only a
alliative procedure (98), 74% died within 1 yr.
ine (12%) of the 73 lived for 2 yr, 2 for 5 and
yr. In the 185 patients undergoing resection or
xtirpation, primary operative mortality was 21%,
nd 5-yr survival rate, 31%. The findings from a
omparable study of 523 patients aged less than
0 yr were significantly less, 8% and 48% respective-
y. Adenocarcinoma patients had the best prognosis,
5-yr survival rate of 34%. The rate in colloidal
arcinoma patients was 18%. Operative mortality in
the 225 patients aged over 70 yr of the colon carcinoma study was 13%. It is concluded that the aged with carcinoma should be treated on the same principles as younger patients.

2194 EPITHELIAL MISPLACEMENT IN ADENOMATOUS POLYPS OF THE COLON AND RECTUM. *(E.)* Greene, F. L. (Yale-New Haven Med. Ctr., Conn.). *Cancer* 33(1):106-217, 1974.

During an 8-yr period, 747 adenomatous polyps were removed either alone or in association with a known colonic cancer and were reviewed to determine whether benign-appearing adenomatous epithelium could be located below the level of the muscularis mucosae (misplacement) unassociated with the additional pathologic signs of invasive cancer. Of 637 polyps unassociated with cancer resection, 3.2% showed evidence of benign "misplacement," while this entity was found in 28% of the adenomas removed in association with 596 resections for cancer. Adenomatous misplacement is associated with cystic dilatation in the polyp head, hemosiderin deposition in the stalk, and normal lamina propria which surround adenomatous tissue appearing below the muscularis mucosa. Cytology of the "misplaced" structures is identical to the benign adenomatous pattern seen on the polyp surface. This entity must be differentiated carefully from the appearance of invasive cancer in adenomatous polyps in order to avoid unnecessary radical colonic resections. Previous statistical analyses regarding the association of gross malignancy and "invasive cancer" in adenomas need to be critically analyzed.

2195 INFLUENCE OF PREOPERATIVE RECOGNITION OF HIGH-GRADE RECTAL CANCERS ON TREATMENT AND RESULTS. *(E.)* Penfold, J. C. B. (St. Mark's Hosp., London, England). *Dis. Colon Rectum* 17(1):47-51, 1974.

The pathologic findings of the excised specimens from 174 cases of high-grade rectal cancer were correlated with the subsequent outcome of the patients. There was 143 excisions and 33 resections. Nearly half of the patients died within the first 12 months. The 5-yr survival was 15%. There were 7 cases of pelvic recurrence, and only 3 of those followed excision of tumors in the upper 66% of the rectum. There was no recurrence in those resected. There were 114 patients whose tumors occurred in the upper two thirds of the rectum and who were thus eligible for either excision or resection. Many of the tumors from the resected cases were average-grade on preoperative rectal biopsy, and only after thorough examination of the operative specimens were the growths assessed as high-grade. There were 72 patients with high-grade tumors in the upper third of the rectum and rectosigmoid. There were 40 with excision and 32 with resection. Of these, 7 of the 40 and 4 of the 32 are alive. There were 29 tumors showing downward spread, which is microscopic tumor below the visible lower edge of the tumor either in the bowel wall or in the surrounding tissues. All of these 29 patients died from cancer. The tumors of the 26 patients who survived 5 yr did not show any downward spread. It is concluded that despite confirmation that high-grade cancers show more extensive local spread, more extensive rectal excisions have not improved results, and may have resulted in increased short- and long-term morbidity.

2196 FAMILIAL DIFFUSE POLYPOSIS OF THE COLON AND RECTUM: SUPPLEMENTARY REPORT ON THREE PEDIGREES. *(E.)* Schutte, A. G. (St. Joseph's Hosp., Milwaukee, Wis.). *Dis. Colon Rectum* 16(6):517-523, 1973.

A supplementary report is presented on familial diffuse polyposis of the colon and the rectum. One of the members of the first family group died at age 54 with a diagnosis of biliary cirrhosis and adenocarcinoma of the common bile duct. No metastatic bowel cancer was found. The oldest of his 4 sons manifested diffuse polyposis at the age of 11 yr. At the age of 12, he underwent colectomy and ileoproctostomy. There was no regression of polyps, and at the age of 19, he had proctectomy and ileostomy. One of the original brothers had diffuse polyposis. After subtotal colectomy and surveillance, he developed adenocarcinoma of the rectum during the sixth decade of his life. He died at about 60 yr of age. Of his 2 children, the daughter was affected with familial polyposis at the age of 17 yr. Another original brother had numerous polyps in all segments of the colon. He died at the age of 40 yr of polyposis and cancer of the midrectum. A son of one of the brothers had subtotal colectomy at the age of 14 yr and proctectomy and ileostomy for rectal cancer when 20 yr old. In the second family group, an examination of the 4 daughters of one of the sisters showed their freedom from inherited polyposis to have persisted to the ages of 41, 39, 37, and 35 yr. An only brother had subtotal colectomy at the age of 16 yr. Only one living sister of 4 remains free of the disease at the age of 53 yr. In the third family group, a 30-yr-old man was seen over a period of 30 years with rectal polyps which were periodically fulgurated. His mother had surgical treatment for an obstructive, metastasizing tumor of the left colon associated with colonic polyposis. A sister is still free of polyposis at the age of 55 yr. Complete regression of polyps following subtotal colectomy with low-level ileosigmoidostomy of ileoproctostomy has not been observed. This study illustrates the variation in the severity of familial polyposis and the unpredictability of its course as found in members of related and unrelated families. After the onset of polyposis, the symptoms which emerge are dependent upon the rate of increase in the number and/or size of the adenomas and/or development of adenocarcinoma.

2197 LOCALIZED ULCERATION OF THE CAECUM DUE TO MICROCIRCULATORY THROMBOSIS: A NEW CONCEPT OF NON-SPECIFIC ULCERATION OF THE CAECUM. *(E.)* Hardie, I. R.; Nicoll, P. (Dept. Surg., Univ. Queensland, Australia). *Aust. N.Z. J. Surg.* 43(2):149-157, 1973.

Case reports of 3 patients with lesions of the cecum are presented. The first case was of a 34-yr-old woman with 2 days' history of colicky abdominal pain, periumbilical at first, but later localized in the right iliac fossa. A diagnosis of subsiding appendicitis was made. At operation there was considerable thickening, edema and inflammation of the anterolateral wall of the cecum adjacent to the appendix, which was distended and tense, but showed only mild serosal inflammation. Crohn's disease was diagnosed and right hemicolectomy performed. She made an uncomplicated recovery. Macroscopically, the cecal wall was thickened, with mucosal congestion and several areas of shallow ulceration immediately distal to the ileo-cecal junction. Microscopically, this ulceration varied from partial to complete, and in adjacent areas there was a slight increase in chronic inflammatory cells, although no evidence of specific colitis. The second case was a 29-yr-old man who had had constant right iliac fossa pain for 4 days, no alimentary upset, and dysuria for 2 days. At laparatomy, there was a moderate amount of free fluid in the peritoneal cavity, and a thickened area in the antero-medial wall of the cecum just above the ileo-cecal junction. Cecotomy was performed, revealing mucosal ulceration on and around this lesion, which was then locally resected. His postoperative recover was uneventful. Macroscopically, the cecal wall was markedly edematous, with partial mucosal ulceration. Microscopically, the upper layers of mucosa were lost with coagulative necrosis of the deeper mucosa. The third case was a 70-yr-old man with 1 week's history of abdominal pain, which began centrally, but later moved to the right iliac fossa, and was associated with anorexia and constipation. At operation for appendicitis, a mass was palpable in the cecal wall ust below the ileo-cecal junction and as carcinoma ould not be excluded resection of the cecum and erminal ileum was performed. Macroscopically, the ass was edematous cecal wall with an indurated ulcer hich on microscopic examination showed loss of the pper layers and coagulative necrosis of the remainder f the mucosa, the muscularis mucosa being intact in ll sections. All 3 patients are well, with no astrointestinal symptoms or signs, after 2, 6, and yr, respectively.

198 SQUAMOUS-CELL CARCINOMA OF THE ANUS. *(E.)*

Failes, D.; Morgan, B. P. (Sydney Hosp., ustralia). *Dis. Colon Rectum* 16(5):397-401, 1973.

retrospective study is presented of 76 patients ith squamous-cell carcinoma of the anus. There ere 11 patients with anal-margin carcinoma. The verage age was 56 yr; 4 were women and 7 were men. hey were treated by a variety of methods: 4 by adiotherapy, 5 by local excision, and 2 by abdomino-erineal excision. Of 9 patients available for 5-yr ollow-up studies, 6 (67%) had survived 5 yr. There ere 65 patients with anal-canal carcinoma, the average ge was 66 yr. There were 41 women and 24 men. espite the accessible nature of these lesions, diagosis was often late, and many tumors were in adanced stages when first seen. Of 12 patients whose esions were suitable for palliative treatment only, nvolved nodes occurred in 5 (41%). Of the remaing 53 patients, such nodes occurred in only 7. The verage survival time for the 12 patients who reeived palliative treatment was 8 months. Radioherapy rarely controlled the disease. Of the 21 ases initially treated by radiotherapy, 18 were vailable for follow-up, but only 3 (17%) could be egarded as having been cured by this means of treatent. The use of radiotherapy with the hope of preerving anal sphincter function and avoiding colostomy as most unsuccessful. Conservation of the sphincter y wide local resection with preservation of part of he sphincter was attempted in 7 patients. Two have urvived for 5 yr. This method cannot be recommended s the primary procedure of treatment for anal-canal esions. In 25 patients radical surgery was performed s the primary treatment. The usual operation was bdomino-perineal resection of the rectum, although patients underwent colostomy followed by perineal xcision of the rectum. Of 19 patients available for -yr follow-up studies, 8 survived 5 yr. Block disection of inguinal lymph nodes was carried out only hen the nodes appeared to be clinically involved. he overall 5-yr survival rate in this series of 59 atients was 37%; for anal-canal lesions, 32%; for nal-margin lesions, 67%. It is concluded that radioherapy is an unsatisfactory method of treatment and hat radical excision is the only method of treatment hich carries reasonable prospects of cure.

199 DEVELOPMENT OF CANCER ASSOCIATED WITH INFLAMMATORY ULCEROHEMORRHAGIC CHANGES IN HE COLON AND RECTUM. *(Ger.)*

Roenspies, U.; aegesser, F. (Dept. Surg., Univ. Lausanne, Switzerand). *Helv, Chir. Acta* 40(5/6):719-726, 1973.

Of 104 patients with ulcerative colitis during a 5-yr period, 6 (mean age 43 yr) developed carcinomas; 2 had carcinomas in 2 different sites (5.4%). Carcinomas developed in 4 of 11 patients who had symptoms for more than 15 yr. The mean time elapsed from onset of ulcerative colitis was 16 yr. Most of the tumors were rectal adenocarcinomas, but 1 tumor was found in the cecum and another in the right colonic flexure. Survival ranged from 5-38 months (mean 17.7 months). Of 21 patients with radiation-induced proctocolitis, 3 developed malignant tumors (2 adenocarcinomas of the sigmoid and 1 peritoneal fibrosarcoma) 8, 4, and 17 yr, resp. after irradiation for primary tumors of the inguinal region, ovary, and corpus uteri. Survival times ranged from 1 to 3 yr. No relation was found between the dose of radiation and development of cancer, but the association between radiation-induced proctocolitis and cancer is not likely to be fortuitous. Of 6 patients with obstructive ischemic colitis, 2 developed carcinomas: an adenocarcinoma of the rectosigmoid and a carcinoma in the left colonic flexure.

2200 SOME CASES OF THE IRRITABLE BOWEL SYNDROME STUDIED BY INTRALUMINAL PRESSURE RECORDINGS. *(E.)*

Champion, P. (Univ. Hosp., Leiden, Germany). *Digestion* 9(1):21-29, 1973.

Intraluminal pressure recordings were used to study some cases of the irritable bowel syndrome. There were 36 cases of irritable bowel syndrome; 20 were studied through the measurement of activity and pressure changes in the lumen of the distal colon using a water-filled polythene manometric system. After a period of rest, the activity of the colon was recorded for 1 hr before and 1 hr after the i.m. administration of 0.1 mg neostigmine. The X-ray findings of a barium enema indicated 19 normal and 17 hyperactive or spastic; of a small bowel enema, 29 normal, and 4 hyperactive or spastic. The pain in the abdomen included the whole abdomen (4); right hypochondrium (2); left hypochondrium (3); right iliac fossa (7); left iliac fossa (6) and suprapubic (10). There were 3 with pain alone, 16 with pain and diarrhea; 4 with diarrhea alone; and 13 with constipation and pain. They varied in age from less than 9 to 49. Personality problems existed in 15 (41%) with diarrhea, and 10 (28%) with constipation. The colon pressure recordings from probable normals with symptoms (7 cases) before neostigmine were: total number of waves (3); average wave time 3.3 sec; and total activity, 108 sec. After neostigmine, the respective numbers were 120, 14.0 sec, and 594 sec. The colon pressure recordings for 6 cases of irritable bowel syndrome between attacks before neostigmine were: total number of waves, 40; average wave time, 15.1 sec; and total activity, 605 sec. After neostigmine, the respective numbers were 171, 24.3 sec, and 4,175 sec. The colon pressure recordings for 4 cases of irritable bowel syndrome with symptoms before neostigmine were: total number of waves, 76; average wave time, 29 sec; and total activity, 2,239 sec. After neostigmine, the respective numbers were 63, 56 sec, and 3,520 sec.

LARGE INTESTINE

Ulcerative Colitis

2254 SIEVING CHARACTERISTICS OF INFLAMED RECTAL MUCOSA. *(E.)* Rask-Madsen, J. (Glostrup Hosp., Denmark). *Gut* 14(12):988-989, 1973.

The sieving characteristics of inflamed rectal mucosa were studied in 3 healthy volunteers and 5 patients suffering from ulcerative colitis localized to the rectum, Gel filtration of urine following rectal instillation of ^{125}I-polyvinylpyrrolidone (^{125}I-PVP) was applied for the estimation of molecular weight distribution of ^{125}I-PVP absorbed from the rectum and excreted by the kidneys during the first 5 hr. The molecular size distribution of labelled PVP in the urine samples taken from the controls following rectal instillation shows only activity in the low molecular weight fractions. The results obtained in the patients with active inflammation of the rectum were similar to those obtained in controls, the clearances of high molecular fractions following rectal instillation being insignificantly different from zero. It is concluded that this study supports the view that the increased permeability of the inflam rectal mucosa to both small charged particles and hydr philic compounds is due primarily to ultrastructural changes rather than to macroscopic defects of the diseased epithelium.

2255 A CONTROLLED THERAPEUTIC TRIAL OF LONG-TERM MAINTENANCE TREATMENT OF ULCERATIVE COLITIS WITH SULPHASALAZINE (SALAZOPYRIN). *(E.)* Dissanayake, A. S.; Truelove, S. C. (Radcliffe Infirm., Oxford, England). *Gut* 14(12):923-926, 1973.

The effect of sulphasalazine on ulcerative colitis was studied in 64 patients in a controlled therapeutic trial. The patients entered into a controlled trial of sulphasalazine versus placebo tablets for a period f 6 months. All the patients admitted were not only ymptom-free but also showed no evidence of inflamation on sigmoidoscopy and rectal biopsy. A patient as judged to have relapsed when there was a recurrence f colitic symptoms accompanied by sigmoidoscopic and istological evidence of inflammation. The patients ho received placebos had more than 4 times the reapse rate of those receiving sulphasalazine. The esults were similar in patients who had been on mainenance treatment with sulphasalazine for less than 3 ears before entry into the trial and in those who ad been on this treatment for more than 3 years. t is concluded that maintenance treatment of ulceraive colitis with sulphasalazine should be continued ndefinitely unless contraindicated by side effects.

PANCREAS

261 FUNCTIONAL STUDY OF EXOCRINE PANCREAS IN IDIOPATHIC HEMOCHROMATOSIS, UNTREATED AND REATED BY VENESECTIONS. HEMOCHROMATOSIS, UNTREATED ND TREATED BY VENESECTIONS. *(E.)* Simon, M.; osselin, M.; Kerbaol, M.; Delanoe, G.; Trebaul, L.; ourel, M. (Hosp. Pontchaillou, Rennes, France). *igestion* 8(6):485-496, 1973.

study was made of the exocrine pancreas, based on he analysis of duodenal juice after secretin (1U/kg) nd CCK (3U/kg) injection in patients with untreated diopathic hemochromatosis (22 cases, 2 females and 0 males, aged 32-36 yr) and in patients treated with epeated venesections (10 cases, 2 females and 8 males, ged 32-60 yr). Comparisons were made with 10 normal ontrols; 13 common cirrhotic patients, 12 of whom ad certain alcoholism and 11 had evident portal ypertension; and 10 subjects with calcified pancreaitis. No clinical symptom of the hemochromatosis atients correlated to pancreatic disease. The volume f duodenal juice collected during 40 min following ecretin injection ranged from a high of 521 ml in ntreated hemochromatosis, 363 ml in cirrhosis, 153 l for venesection-treated hemochromatosis (not signiicantly different from controls, 169 ml) to 79 ml or calcified pancreatitis patients. Maximum bicaronate concentration after secretin dropped from conrol values of 99.5 mEq/l to 62 mEq/l in untreated emochromatosis, 60 mEq/l in cirrhosis and 75 mEq/l n treated hemochromatosis. Maximum bicarbonate output fter secretin was not significantly different in reated hemochromatosis (3.3 mEq/10 min) and controls 4.6 mEq/10 min), but measured 10.2 mEq/10 min in unreated hemochromatosis and 8.5 mEq/10 min in cirrhosis. fter CCK the maximum lipase concentration in treated hemochromatosis was 116.5 U/ml, not significantly different from controls, but the figures in untreated hemochromatosis were 94U/ml and for cirrhosis, 98.5 U/ml. It was concluded that the secretory characters of untreated idiopathic hemochromatosis are not important in the increase of iron absorption.

2262 UPTAKE OF METHYLCHOLANTHRENE IN THE RAT PANCREAS. *(E.)* Black, Jr., O.; Webster, III., P. D. (VA Hosp., Augusta, Ga.). *Am. J. Dig. Dis.* 19(1):37-42, 1974.

The chemical carcinogen, ^{14}C-3-methylcholanthrene (5μ Ci, i.p.), was injected into white, male, Sprague-Dawley rats to determine to what extent rat pancreas sequesters and metabolizes this drug. The carcinogen was taken up in the pancreas to the same degree as the liver on a per gram wet weight basis. The greatest percent of radioactivity, 41%, appeared in the nuclear and cell membrane fractions. The next highest, 27%, appeared in endoplasmic reticulum. Only 17% remained in the supernatant fraction. Maximal incorporation occurred around 36 hr following administration. Ether extracts of homogenates revealed that few breakdown products were formed even up to 48 hr after injection. It appears that rat pancreas sequesters 3-methyl-cholanthrene but has little metabolizing capacity.

2263 DIFFERENTIAL DIAGNOSIS OF TUMORS IN THE HEAD OF THE PANCREAS DURING SURGERY: RESULTS OF CONVENTIONAL HISTOLOGICAL AND MODERN CYTOLOGICAL EXAMINATIONS. *(Ger.)* Bodner, E. (Surg. Clin., Univ. Innsbruck, Austria). *Langenbecks Arch. Chir.* 333(3):165-190, 1973.

The results of preoperative diagnostic techniques were poor in 107 patients (67 men and 40 women, aged 38-87 yr) with tumors of the head of the pancreas; 79 had carcinomas and 19 had inflammatory tumors. Pathological findings were obtained in 17 of 91 patients by studies of gastroduodenal transit, in 8 of 21 patients by hypotonic duodenography, in 18 of 31 by pancreatic scintigraphy, in 7 of 18 by celiac-mesenteric arteriography, and in 15 of 22 by the pancreozymin-secretin test. At the first operation a definitive diagnosis of carcinoma was established only in 39 of 79 patients; 23 already had gross evidence of metastases and a diagnosis was established by histological examination of the primary tumor in 16. In 38 more patients tumors were diagnosed at pancreatoduodenectomy, at subsequent laparotomy, or at autopsy. Diagnoses were established only by clinical follow-up in the remaining 30 cases; the diagnosis is still unconfirmed in 9. Complications developed in 15 of the 37 patients who had conventional biopsies. The most common complication was pancreatic fistula which developed in 11 patients; 9 fistulas healed spontaneously but 2 persisted until the patients died. Other complications consisted of subphrenic abscesses (2 patients), WBC elevation (7), bleeding (1), and death (1). Cytological examinations were made by 4 different techniques (preoperative examination of duodenal juice and examination of pancreatic juice, pancreatic duct smears, and fine-needle suction biopsies obtained during surgery) on 36 patients. These consisted of 19 with malignant tumors of the head of the pancreas, 10 with pancreatic pseudocysts, and 7 controls. The best results were obtained with biopsies. Positive diagnoses of malignancy were established in 11 and possible diagnoses of malignancy in 4 patients with pancreatic carcinomas; results could not be evaluated in 7 of the 10 patients with pseudocysts due to the presence of blood and detritus in the sample. No false-positive results were obtained. Although a few patients had elevated urinary diastase and α-amylase levels after biopsy, these never reached alarming values.

2264 RESECTABILITY AND PROGNOSIS OF CARCINOMA OF THE PANCREAS EVALUATED BY ANGIOGRAPHY.

(E.) Tylen, U.; Arnesjo, B. (Univ. Hosp., Lund, Sweden). *Scand. J. Gastroenterol.* 8(8):691-697, 1973.

Results of angiographic examination of the pancreas were correlated with resectability and survival of 116 patients with verified carcinoma of the pancreas or the periampullary region. Among 56 patients with encasement of extrapancreatic arteries or the gastroduodenal artery, radical tumor removal was possible in only 8 and survival time was always less than 1 yr, usually less than 6 months. In 26 patients with encasement of the gastroduodenal artery, resection was possible in 6 and none survived 12 months. This survival time differed only slightly from patients with the same angiographic findings in whom resection was impossible. It is however advised that patients with involvement of the gastroduodenal artery but not extrapancreatic arteries be explored and radical resection attempted as this is the most beneficial palliative measure against pain available. Tumor encasement of small arteries or with tumor vessels occurred in 60 patients and radical resection was possible in 25 of whom 6 died postoperatively. The longest survival time thus far is 9 yr, for a patient with carcinoma at the papilla of Vater. Survival of more than 2 yr occurred in 7 patients. These results illustrate the poor prognosis of patients with carcinoma of the pancreas and periampullary region. The good correlation between the extension of angiographic changes and the extension of tumor growth makes angiography useful in the preoperative evaluation of pancreatic carcinoma.

2265 MAXIMUM BICARBONATE RESPONSE TO INTRAVENOUS INFUSION OF 'GIH' SECRETIN IN MAN. *(E.)*

Gutierrez, L. V.; Baron, J. H. (Roy. Postgrad. Med. Sch., London, England). *Clin. Sci. Mol. Med.* 45(6): 859-862, 1973.

Studies were made of the pancreatic bicarbonate response to GIH infusion in 6 subjects without pancreatic disease, 1 with chronic pancreatitis and 2 with carcinoma of the pancreas. In 21 tests the maximum volume and bicarbonate output of the duodenal aspirate in response to i.v. infusion of pure GIH secretin was significantly higher with 4 than with 1 or 2 units/kg-hr, and there was no consistent change in these outputs after 8 units/kg-hr. Tryptic activity was lower in each subject after 2 than 1 unit/kg-hr and lower still after 4 units/kg-hr with no significant change occurring after 8 units/kg-hr. The optimum maximum dose of secretin in man is probably 4 units/kg-hr. The highest dose, 8 units/kg-hr, was tested only in subjects without pancreatic disease.

2266 PANCREATIC REFLUX DURING OPERATIVE CHOLEDOCHOGRAPHY. *(E.)*

Cuschieri, A.; Hughes, J. H. (Dept. Surg., Univ. Liverpool, England). *Br. J. Surg.* 60(12):733-736, 1973.

The incidence and significance of pancreatic reflux was studied in 211 consecutive cases undergoing elective cholecystectomy where an operative choledochogram was performed using either hand or pump injection of dye. The age range of patients was 28 to 72 yr. Reflux of contrast medium into the pancreatic duct occurred in 23 out of 166 cases of hand injection (13. and in 8 out of 45 consecutive cases of pump injection (17.7%). Out of the total 211 cases, 1 patient developed acute pancreatitis after surgery with a rise in the serum amylase of 2050 Somogyi units per 100 ml. Eight out of the 31 pancreatograms obtained showed an abnormal pancreatic duct. There were 18 cases of ductal stones and pancreatic reflux was present in only 1 of these. Reflux of sodium diatrizoate into the pancreatic duct was observed in 8 cases where dynamic pressure changes could be monitored simultaneously in the common-bile-duct and second part of the duodenum. In these cases, pancreatic reflux was associated with a low resting choledochal pressure. No association was found between ductal stones and reflux of dye into the common bile-duct. Pancreatic reflux was associated with a low biliary pressure and segmental duodenal activity.

276 INTESTINAL OBSTRUCTION DUE TO ACUTE PANCREATITIS. CASE REPORT AND REVIEW OF ITERATURE. *(E.)* Agrawal, N. M.; Gyr, N.; McDowell, .; Font, R. G. (VA Hosp., New Orleans, La.). *Am. . Dig. Dis.* 19(2): 179-185, 1974.

he case of a patient who presented with complete uodenal and partial colonic obstruction is reported. he patient, a 33-yr-old negro male, known alcoholic, omplained of periumbilical pain for 3 days and onstipation of 5 days duration. An upper GI series evealed crescent-shaped obstruction at the beginning f the second portion of the duodenum and markedly elayed passage of barium into the jejunum. Duoenoscopy showed complete obstruction of the duodenum 0 cm beyond the pyloric opening. Submucosal hemorhages were present all over in the duodenum. The uodenal mucosa was intact. During exploratory aparotomy, an inflammatory mass was found in the ight upper quadrant involving the hepatic flexure, mall bowel, and the omentum. On separation of the mall bowel and the colon from the mass, two areas f chocolate-colored fluid collection were found in he adhesions. The peripancreatic peritoneal fibrous eaction and adhesions were obstructing the second ortion of the duodenum. Gastrostomy was performed nd a feeding tube was passed through the stomach and the duodenum into the jejunum. On the twelfth postoperative day, the gastrostomy tube was removed and the patient could eat without any difficulty. Acute pancreatitis can be associated with a variety of complications, such as obstructive jaundice, pseudocyst of the pancreas, pancreatic abscess, pancreatic fistula, hemorrhage, shock, ascites, and pleural effusion with a mortality of about 5%. Intestinal obstruction is an uncommon complication of pancreatitis. This patient is the first case where simultaneous obstruction at two different sites in the gastrointestinal tract has been documented. Obstructions have occurred in: the splenic flexure (13 cases) transverse colon (1 case); hepatic flexure (1 case); descending colon (1 case); ileum (1 case); jejunum (1 case); and duodenum (5 cases).

97 THE AMINO ACID NAPHTHLAMIDASE REACTION OF
THE BILE CANALICULI IN LIVER SMEARS. *(E.)*
sastjerna, C.; Ekelund, P. (Kivela Hosp., Hel-
nki, Finland). *Acta Cytol.* 18(1):23-29, 1974.

tologic air-dried smears from human, rat and
inea pig livers were stained for amino acid
phthylamidase activity with alanyl-4-methoxy-2-
phthylamide as the substrate. The liver cells
unfixed smears displayed a granular cytoplasmic
action, but no canaliculi were observable. Pre-
eatment with acetone-chloroform, and some other
pid solvents, eliminated the intracellular stain-
g, but it was required for staining of the bile
naliculi. These were visible as uniformly-stained,
rk red bands, about twice the width of those
en by staining for adenosine triphosphatase. The
nalicular amino acid naphthylamidase of air-dried
ver smears was resistent to dry heat and to p-
loromercuribenzoate. The enzyme was completely
hibited by EDTA and Hyamine, and partly by
romycin. The results with leucyl-beta-napthyl-
ide as substrate were similar. Smears of human
le exhibited a strong alkaline phosphatase, a
ak or negative amino acid naphthylamidase reac-
on and no adenosine triphosphatase activity. The
ino acid naphthylamidase staining of liver cell
ears fixed with acetone-chloroform provides a
itable mens for cytologic study of the bile cana-
culi, which is valuable in the diagnosis of
olestasis, hepatitis, and carcinoma.

98 STUDIES OF LIPOPROTEIN-X (LP-X) AND BILE
ACIDS IN FAMILIAL LCAT DEFICIENCY: PRE-
MINARY REPORT. *(E.)* Gjone, E.; Javitt, N. B.;
omhoff, J. P.; Flausa, O. (Univ. Hosp., Rikshosp.,
lo, Norway). *Acta Med. Scand.* 194(5):377-378,
73.

e serum bile acid concentration and composition
re investigated in 5 Norwegian patients with
milial LCAT deficiency and the presence of lipo-
otein-X (LP-X) in their serum was studied. Bile
mposition was studied in 2 of them. LP-X was
monstrated in serum from all 5 patients. All had
evated free cholesterol and markedly reduced con-
ntrations of cholesteryl ester. LCAT activity
s not detected in serum of any of them. Serum
iglycerides were high in all, as were also total
ospholipids. Elevated concentrations of serum
ic acid and acid phosphatasis were found in 3 of
e patients. The serum bile acid studies showed
at all patients had normal total concentration.
ne of the patients had any sign of liver or biliary
act disease. The bile composition as studied in
llbladder bile and duodenal bile respectively,
om 2 patients had a normal composition of bile
ids and lipids. It is concluded that these find-
gs show that factors other than biliary obstruc-
on and serum bile acid accumulation may be respons-
le for the formation of LP-X in serum. The finding
bile acids (particularly lithocholic acid) bound
LP-X in patients with liver disease and high
rum bile acid levels may probably represent a non-
ecific binding.

2299 DELTA-AMINOLEVULINIC ACID DEHYDRATASE ACTIVITY OF ERYTHROCYTES AND LIVER TISSUES IN MAN. RELATIONSHIP TO LEAD EXPOSURE. *(E.)* Secchi, G. C.; Erba, L.; Cambiaghi, G. (Inst. Occupational Health, Univ. Milan, Italy). *Arch. Environ. Health* 28(3):130-132, 1974.

The delta-aminolevulinic acid dehydratase (ALAD) activity of erythrocytes and of liver tissue was studied in 22 subjects not occupationally exposed to lead. A considerable heterogeneity in the levels of ALAD activity of erythrocytes and of blood lead was confirmed in this group of subjects, an expression of the varying degree of absorption of lead that occurs in each individual who is exposed through pollution of the atmosphere and food. In the group of subjects studied, there was a correlation between the values of erythrocyte ALAD activity and the values of ALAD activity of liver tissue.

2300 HEPATIC CELLULAR RESPONSES TO LIVER CANCER: ABNORMALITIES IN METABOLISM OF MITOCHONDRIA ISOLATED FROM HUMAN LIVER INVOLVED WITH CARCINOMA. *(E.)* Ozawa, K.; Kitamura, O.; Yamaoka, Y.; Kamano, T.; Mizukami, T.; Takeda, H.; Takasan, H.; Honjo, I. (Kyoto Univ. Fac. Med., Japan). *Ann. Surg.* 179(1):79-87, 1974.

To clarify the hepatic cellular responses to liver cancer, a biochemical analysis of liver mitochondrial metabolism was made on 44 biopsy specimens of liver with primary and secondary cancer. In the mitochondria from hepatic tissues with multiple nodules scattered throughout both lobes, the concentrations of cytochromes $a(+a_3)$ and b were decreased to less than about 50% of controls and their phosphorylation rates were severely inhibited. The mean survival for those patients surviving the postoperative days was 19 days. On the other hand, in hepatic tissues with massive tumor restricted to one lobe the concentrations of respiratory enzymes and the phosphorylation rates of the mitochondria from the lobe bearing cancer were decreased, while those of the mitochondria from the lobe without cancer were remarkably increased in a compensatory manner. Those patients lived more than 3 months. However, when such an increase in the lobe without cancer could not be demonstrated, those patients had relatively short survival. From the results, it has been suggested that an alteration of hepatic parenchyma around tumor leading to the functional state of depressed aerobic phosphorylation precedes an enhancement of tumor growth and may provide the hepatic soil favorable to enhanced tumor growth and the augmentation of hepatic metastases.

2301 ON THE PATHOLOGICAL MODIFICATION OF SERUM HIGH DENSITY LIPOPROTEINS IN LIVER DISEASES. AN ALTERATION IN THE BINDING MODE OF INDOCYANINE-GREEN WITH HUMAN SERUM PROTEINS. *(E.)* Tanaka, N.; Kanai, K.; Oda, T. (Fac. Med., Univ. Tokyo, Japan). *Clin. Chim. Acta* 49(3):333-340, 1973.

Changes of the binding mode of an anionic dye, indocyanine-green (ICG), with serum proteins in liver diseases are presented. Blood was obtained from patients fasted overnight. A total of 137 sera were investigated, consisting of 12 cases of acute viral hepatitis, 37 of chronic hepatitis, 22 of carbohydrate-induced fatty liver, 34 of liver cirrhosis, and others. In normal subjects, 3 distinct peaks of proteins (19S, 7S, 4S) were observed in gel filtration chromatography. These peaks were also separated in case of ICG (Peak I, II, III). In liver diseases in which no Peak II existed, it did not reappear even when the concentration of ICG was increased. Peak II completely disappeared at the onset of acute virus hepatitis, reappeared slightly in a recovery stage, and returned to normal when the patient completely recovered. Liver cirrhosis and primary hepatoma showed no Peak II. Peak II decreased apparently in most cases of chronic hepatitis. In normal subjects, proteins mainly responsible for ICG binding in Peak I were very low density lipoproteins and low density lipoproteins, in Peak II, high density lipoproteins, and in Peak II, albumin. In liver diseases in which Peak II was not recognized, a high density lipoprotein was found at the 19S site by chromatographic analysis and this high density lipoprotein had the characteristics of an α-lipoprotein electrophoretically. The chromatographic patterns presented in patients with carbohydrate-induced fatty liver were not different from those of normal subjects. The differences in binding changes may be helpful in differentiating carbohydrate-induced fatty liver from other disease of the liver.

2302 AUTORADIOGRAPHIC LOCALIZATION OF INTRACELLULAR α-FOETOPROTEIN IN PRIMARY LIVER CANCER IN MAN.

(E.) Uriel, J.; Loisillier, F.; Szekely, A. M.; Bismuth, H. (Inst. Res. Sci. Cancer, Villejuif, France). *Biomedicine* 21:21-25, 1974.

α-Fetoprotein was localized by cell affinity labeling with tritiated estrogens in a hepatocellular carcinoma from a 31-yr-old man. Tumor biopsy was obtained in the course of abdominal operation. Liver histology showed a multifocal hepatocellular carcinoma with pronounced polymorphism. Areas of well differentiated trabecular hepatoma alternated with large nests of small or giant cells, frequently having a trabecular architecture, and with zones of macronodular cirrhosis probably of postnecrotic origin. After incubation with tritiated estrogens, radiolabelled cells were found in different areas of the tumor section: 1) in zones of bile-duct proliferation in the vicinity of portal tracts; 2) disseminated among neoplastic trabeculae most frequently at the border of sinusoid capillaries or protruding into the lumen; 3) entrapped within areas of fibrous connective tissue together with spindle-cells and cells of ductular morphology. Kupffer cells and cuboidal cells lining bile ducts were devoid of radioactivity. Radioactivity was concentrated in the cytoplasm or at the cytoplasmic membrane of well individualized single or thinly scattered groups of cells. Whatever the site of localization, the morphology of the labeled elements was very similar: small round or oval cells with an elongated or kidney-shaped nucleus. The total number of radiolabelled cells per tumor section was relatively low, about 1 to 2% of the whole liver cell population. The hypothesis is advanced that α-fetoprotein probably is transitorily produced by a transitional cell implicated in liver ontogeny and regeneration.

2303 PRIMARY CARCINOMAS OF THE LIVER IN HONG KONG: SOME POSSIBLE AETIOLOGICAL FACTORS.

(E.) Gibson, J. B.; Chan, W. C. (Dept. Pathol., Univ. Hong Kong). *Recent Results Cancer Res.* 39:107-118, 1972.

Some possible etiological factors concerning primary carcinomas of the liver are discussed. In Hong Kong, about 17% of primary liver cancers are of bile-duct type; however, the ratio of cholangiocarcinoma to liver-cell carcinoma is about the same as in the West. Evidence has been collected which points to the association of intrahepatic-bile-duct carcinoma with oriental distomiasis. The liver fluke responsible for infections is Clonorchis sinensis. In Hong Kong, flukes are found in about 23% of the cases that are over 2 yr of age. Cholangiocarcinoma is diagnosed in Hong Kong almost exclusively in persons over 40 yr of age; it seems that the carcinogenic action of distomiasis works slowly. How clonorchiasis brings about its carcinogenic effect is unknown. Oriental distomiasis is associated with a proliferation of the biliary epithelium, with an enhancement of the mucus secretion and with the new formation of goblet cells in segments of the ducts in the immediate vicinity of the flukes. This type of carcinoma in the liver is often mucin-producing. Cholangiofibrosis presents mucin that is identical in histochemical reactions with that produced normally in the common bile duct of the rat. Therefore, cholangiofibrosis may be a precursor of the bile duct tumors that sometimes occur in place of the more usual hepatocellular tumors in experimental carcinogenesis, and particularly when butter yellow is employed. In Hong Kong, liver-cell carcinoma is commoner than cholangiocarcinoma, and clonorchiasis, schistosomiasis and other forms of parasitism play no demonstrable part in the etiology. In experiments with chemical carcinogens on rats, it is common to find that effective agents can produce either cirrhosis or carcinoma or both. When diethylnitrosamine is given to young male rats, hepatocellular carcinomas are induced within a few months. Cirrhosis in Hong Kong is not very different from that seen in other tropical locations. In the search for a causitive factor in human liver cancer, the heaptotoxic elements in the environment have to be considered. A naturally occurring biological product, pyrrolizidine alkaloids, has attracted considerable attention as a source of chronic liver disease but its importance is still not settled. Another source of hepatotoxic agents is contamination of food by toxigenic fungi, such as *Penicillium Islandicum, Aspergillus Flavus, Fusarium,* and *Rhizopus*. In Southeast Asia, it appears that contamination of foodstuffs with aflatoxins is likely to prove of significance in the etiology of liver cancer.

2304 SPONTANEOUS RUPTURE OF HEPATOMA: A MISDIAGNOSED SURGICAL EMERGENCY. *(E.)*

kezie, O.; DeAngelis, G. (Queens Hosp. Ctr., amaica, N.Y.). *Ann. Surg.* 179(2):133-135, 1974.

hree case reports are presented of spontaneous upture of hepatoma. There are no pathognomonic igns, symptoms, or laboratory indices of hepatoma. he relevant laboratory findings for the 3 patients re: total bilirubin, 0.7, 3, and 1.5; alkaline hosphate, 12.5, 19, and 47; albumin, 3.1, 2.5, and .2; cholesterol, 170 and 153; SGOT, 25, 221, and 5; Prothrombin time, 13.5/13 and 15/14; glucose, 4 and 80; hematocrit, 31%, 44.7-24%, and 28%; and eucocyte, 7,000, 5,700, and 23,000. The disease imics other conditions and rarely presents as an cute abdominal catastrophe. These three patients ere apparently well and all presented with acute bdomen due to the spontaneous rupture of a hepatoma. he unsuspected diagnosis was established at laparoomy. Hepatoma is intimately associated with liver irrhosis and hemochromatosis, and has a prediliction or middle-aged and elderly men. The three cases ere all male, 50, 53, and 65 yr old. Patients 1 nd 2 had cystic lesions, biopsies of which were istologically hepatomas. Patient 3 was not an aloholic, but all 3 demonstrated cirrhosis at biopsy.

305 THE SURGICAL ANATOMY OF THE HEPATIC VEINS: VARIATIONS AND THEIR IMPLICATIONS FOR AUXILARY LOBAR TRANSPLANTATION. *(E.)* Baird, R. A.; ritton, R. C. (no affil.). *J. Sur. Res.* 5(5):345-347, 1973.

n anatomic study of the hepatic veins was undertaken to determine the feasibility of hepatic lobe ransplantation using living donors. Vinylite corroion casts were made of 74 human livers obtained at utopsy. The right lobe was drained by both the ight hepatic vein and the median vein. It was also requently drained by other variously sized veins uch as the dorsal inferior and the dorsolateral ight hepatic veins which enter the vena cava along ts perihepatic length. The left lobe was drained y one or more veins that enter the vena cava either irectly or through a common trunk with the median ein. A common trunk was present in 94% of casts nd varied in length from 2 to 22 mm; the mean length as 10 mm. It most often comprised the confluence f the median and a single left hepatic vein. In 9% f the cases, the inferior segment of the left lobe rained into a peripheral, or distal, branch of the edian vein.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

314 HEPATIC CLEARANCE OF UNCONJUGATED BILIRUBIN IN CHOLESTATIC LIVER DISEASES. *(E.)* loomer, J. R.; Berk, P. D.; Howe, R. B. (Yale Univ. ch. Med., New Haven, Conn.). *Am. J. Dig. Dis.* (1):9-14, 1974.

e hepatic clearance of unconjugated ^{14}C-bilirubin om the plasma of 5 patients with cholestatic liver disease was normal when compared with values obtained in 28 healthy young adults. In 1 patient with benign recurrent cholestasis, clearance was the same during an attack of cholestasis (serum bilirubin concentration 25.7 mg/100 ml) as when the patient was in remission (serum bilirubin concentration 0.65 mg/100 ml). This study indicates that factors other than abnormal hepatic function should be considered with a patient with predominantly cholestatic liver disease manifests an increased plasma concentration of unconjugated bilirubin. Shortened red-cell life spans in 2 patients (20 and 16 days, Resp.) suggest that increased bilirubin production due to red cell hemolysis may contribute to the unconjugated hyperbilirubinemia. Increased bilirubin production in cholestatic patients could also be due to enhanced turnover of hepatic heme compounds, since hypertrophy of the hepatic smooth endoplasmic reticulum occurs in the cholestatic animal. In some cases, elevations in the indirect-reacting fraction of unconjugated bilirubin may reflect an artifact of methodology.

2315 MATERNAL HYPERBILIRUBINEMIA AND THE NEWBORN. *(E.)* Lipsitz, P. J.; Flaxman, L. M.; Tartow, L. R.; Malek, B. K. (Beth Israel Med. Ctr., New York, N.Y.). *Am. J. Dis. Child.* 126:525-527, 1973.

This report describes the effect of severe maternal hyperbilirubinemia (total bilirubin value, 40 mg/100 ml, of which about 30 to 40% was unconjugated) on the fetus for 3 weeks prior to delivery. Maternal history included sickle-cell disease. The newborn at delivery had a value of 9.8 ml/100 ml for cord blood unconjugated bilirubin (total bilirubin value, 10.4 mg/100 ml; conjugated, 0.6 mg/100 ml) which was similar to the maternal serum value of 11.0 mg/100 ml on the day of delivery. This phenomenon may indicate maternal to fetal transfer of unconjugated bilirubin. It is suggested that equilibration of fetal and maternal circulation of unconjugated bilirubin may occur. However, it is also possible that the elevated unconjugated bilirubin concentration in the maternal blood may have restricted transfer of fetal bilirubin across the placenta. The newborn developed hyperbilirubinemia for which exchange transfusions were required. He also manifested *Escherichia coli* septicemia and expired 46 hr after birth as a result of infection. The autopsy findings revealed no evidence of bilirubin encephalopathy. The hyperbilirubinemia in the infant was likely due either to prematurity, bacterial sepsis, or both.

2316 EVALUATION OF HEPATOTOXICITY OF A DRUG IN PRISON INMATES. *(E.)* Cucinell, S. A. (Walter Reed Army Inst. Res., Washington, D.C.). *J. Clin. Pharmacol.* 14(1):58-60, 1974.

The abnormalities observed during the course of experiments with prison inmates may be due to the prevalence of hepatitis. Fifty-eight men volunteered for the study of the antimalarial drug 4,4'-sulfonylbisformanilide (DPD). Thirteen had elevations of the SGOT, alkaline phosphatase, or both and were not accepted. Only 2 applicants gave a history of hepatitis. However, 20% of the men admitted a history of drug use. There was no relationship between a history of drug use and abnormal liver function tests among the men accepted for the study. There was no tendency for the alkaline phosphatase to rise during the drug treatment period. The SGOT also tended to be high in most volunteers, but only applicants with an initial level under 40 U/ml were placed on the test. Four individuals of the 45 under study had elevations of SGOT during the study. In one man, DFD was stopped. Two others were receiving only placebo, and the fourth man was continued on DFD. The SGOT returned to normal in all. The 4 men who had an elevation of SGOT while on the study admitted drug use in the past. The 4 individuals with elevation of SGOT during the test had no comparable increase in alkaline phosphatase. The abnormalities observed may be due to the prevalence of hepatitis.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

2319 CHOLESTATIC NON-ANGIOCOLITIC HEPATITIS WITH XANTHOMATOSIS, AND CIRRHOSIS. *(Fr.)* Caroli, J.; Nusinovici, V.; Ben Amar, A.; Levy, V. G. (St. Antoine Hosp., Paris, France). *Ann. Med. Interne (Paris)* 124(11):761-770, 1973.

During an epidemic of cholestatic hepatitis, 6 of 50 patients developed periportal fibrosis, severe hyperlipemia, and xanthomatosis. Of these 6 patients, all were women and 5 were aged 40-50 yr. This form of hepatitis was associated with drugs (estrogen-pro-

estagen, antitussive agent, unspecified i.v. in-
ections in 3 cases. None of the patients had a
istory of pruritis or Australia or antimitochondrial
ntibodies. The liver became enlarged only after
-12 months and xanthomatosis, which varied greatly
n its severity, developed after 7-14 months. Jaun-
ice regressed spontaneously or after therapy in all
ases. Other signs included melanoderma, regressive
scites, finger clubbing, and cancer of the thyroid
ith xanthomatosis of metastatic lymph nodes (1 case
ach). Serum bilirubin values ranged from 20.1 to
.0 mg/100 ml and total lipids, from 36 to 75 g/li-
er. Serum bilirubin values reached a maximum af-
er 8-10 months and blood lipids, somewhat later.
ipoprotein X was detected only when blood lipid
evels were greater than 15 g/liter. Biliary tract
bstructions were ruled out at laparotomy in all
ases. Liver biopsies showed that the initial lesion
onsisted of massive cholestasis with obliteration
f intralobular bile ducts in the portal spaces.
eriportal fibrosis developed after 4 months and,
n 2 cases, was preceded by necrosis. This fibro-
is remained mild in 2 cases, but became progressive-
y more severe and tended to dissect the lobule in
he 4 remaining patients. Prolonged administration
f phenobarbital (initial dose of 6-10 mg/kg) to
 of these patients relieved the pruritis, jaundice,
nd reduced blood lipid levels; 3 of these patients
eveloped side effects. Glutethimide (15 mg/kg),
iven to 3 patients, reduced blood lipid levels but
ad no effect on pruritis. External bile drainage
3 cases), corticosteroids (1 case), and long courses
f cholestyramine (6 cases), which are effective
gainst less severe forms of cholestatic jaundice,
aused no improvement in patients with this form of
holestatic hepatitis.

320 ASPIRIN HEPATITIS. *(E.)* Wolfe, J. D.;
Metzger, A. L.; Goldstein, R. C. (Univ.
alifornia Med. Ctr., Los Angeles). *Ann. Intern.
ed.* 80(1):74-76, 1974.

 20-yr-old woman with systemic lupus erythematosus
eveloped hepatitis while on high-dose aspirin thera-
y (975 mg every 4 hr, for a total of 4.8 g/day). Liver
unction tests showed SGOT was 360 IU/ml; SGPT, 168
U/ml; and alkaline phosphatase, 197 IU/liter. The
erum salicylate level was 45 mg/100 ml. Liver func-
ion returned to normal when aspirin therapy was
iscontinued. Subsequent rechallenge with aspirin
4.8 g/day) resulted in hepatitis. SGOT and SGPT
ere 670 and 300 IU/ml, resp., and alkaline phospha-
ase was 205 IU/liter. Serum salicylate was 31 mg/
00 ml. Microscopic examination showed focal hepa-
ocellular necrosis and mild portal, lobular, and
entrolobular infiltration with neutrophils, lympho-
ytes, plasma cells, and histiocytes. There was no
vidence of chronic liver disease or vasculitis.
ince the exact frequency, susceptible population,
nd pathogenetic mechanism of salicylate-induced
epatotoxicity are unknown, serum salicylate levels
nd liver function should be monitored in patients
n high-dose salicylate therapy.

321 DISORDERED HEMOSTASIS IN LIVER DAMAGE FROM PARACETAMOL OVERDOSE. *(E.)* Clark, R.; Borirakchanyavat, V.; Gazzard, B. G.; Rake, M. O.; Shilkin, K. B.; Flute, P. T.; Williams, R. (King's Coll. Hosp. Med. Sch., London, England). *Gastroenterology* 65(5):788-795, 1973.

Coagulation disturbance and radioactive fibrogen turnover were studied in 36 patients (aged 15-58 yr) with hepatic damage due to an overdose of acetaminophen (13-50 g). Based on maximum serum bilirubin value, the patients were divided into 3 groups (A, B, and C) representing mild, moderate and severe liver injury. Group A patients had ← 1 mg serum bilirubin/100 ml; group B, 1-4 mg/100 ml; and group C, → 4 mg/100 ml. Prothrombin time was significantly abnormal in group A, but the greatest change occurred in group C patients. Partial thromboplastin time was markedly prolonged only in the C group. Individual clotting factors, assayed in 9 patients, fell in order of their half-lives. Mean values for thrombin clotting time were prolonged only in group C, in which mean plasma fibrogen values were below normal. Fibrogen-fibrin degradation products were within normal range in group A, increased in half of the B group patients, and most frequently present in C group patients. Plasma half-life of ^{125}I-fibrogen was decreased in 8 of 12 cases studied, indicating an increased rate of disappearance from the circulation. Fibrogen synthesis was normal in 3 cases tested in group A and increased in 4 of 6 cases from groups B and C. These results indicate a positive relation between the severity of liver disease and the degree of coagulation abnormality. However, the changed pattern of coagulation disturbance with increasing hepatic damage suggests that intravascular coagulation is also present. This intravascular coagulation is implicated in increased loss of fibrogen.

2322 ENZYME PATTERNS REFLECTING HEPATIC RESPONSE TO ANESTHESIA AND OPERATION. *(E.)* Thompson, D. S.; Greifenstein, F. E. (VA Hosp., Little Rock, Ark.). *South. Med. J.* 67(1):69-74, 1974.

SGPT, SGOT, and serum ornithine carbamoyl transferase (SOCT) determinations were carried out in 159 men (aged 23-78 yr) before and after operations involving various anesthetic agents and different sites. SGPT values increased significantly on all days following operations in the upper abdomen, and on postoperative day 7 following operations at sites other than the upper abdomen. SGPT increases were greatest following halothane and methoxyflurane. Although differences between these agents were not significant, the only extreme SGPT elevations were associated with halothane anesthetics. These occurred on day 7 following vagotomy and pyloroplasty and on day 7 following a cervical fusion. Enzyme elevation associated with spinal anesthesia occurred after an inguinal herniorraphy and 2 transurethral prostatic resections. No SGPT value exceeded the normal range following cyclopropane anesthesia. There was good agreement between SGPT values measured colorimetrically and those determined by the ultraviolet or spectrophotometric method. SGPT values correlated positively with SGOT and SOCT, indicating that SGPT is a reliable indicator of hepatocellular damage in the postoperative period. Higher enzyme values associated with halogenated hydrocarbons may be due to unknown metabolites.

2323 ASPIRIN-INDUCED HEPATOTOXICITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS. *(E.)*

Seaman, W. E.; Ishak, K. G.; Plotz, P. H. (Natl. Inst. Health, Bethesda, Md.). *Ann. Intern. Med.* 80(1):1-8, 1974.

Patients (3 females, aged 19-29 yr) with systemic lupus erythematosus had liver injury related to aspirin therapy, 2-4 g/day over 1-8 months. The extent of liver damage in these cases was dose-related and improvement was noted on cesation of aspirin intake even before salicylate levels returned to normal, thus ruling out the possibility of an allergic reaction. In 2 patients, the initial presentation mimicked chronic active hepatitis. A liver biopsy obtained from 1 patient was also consistent with the diagnosis of chronic active hepatitis, and the biopsy from the second showed acute hepatocellular injury. In 2 patients SGOT and SGPT values increased, and in the third the alkaline phosphatase value increased as well. Aspirin should be considered among causes of hepatitis, particularly in patients with lupus erythematosus. Aspirin challenge was offered in each of these cases and it is suggested that this be done whenever the diagnosis is in doubt. Any abnormalities occurring in liver functions as a result of this challenge will normalize on drug withdrawal.

2324 RICKETTSIAL HEPATITIS IN "Q" FEVER.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

2325 FULMINANT HERPESVIRUS HOMINIS HEPATITIS DURING PREGNANCY. *(E.)*

Goyette, R. E.; Donowho, Jr., E. M.; Hieger, L. R.; Plunkett, G. D. (Brooke Gen. Hosp., Fort Sam Houston, Tex.). *Obstet. Gynecol.* 43(2):191-196, 1973.

Following exposure to her 2-yr-old son with herpetic gingivostomatitis, a 23-yr-old woman in the 28th week of pregnancy developed *Herpesvirus hominis* (herpes simplex virus) hepatitis and died 2 weeks later. Previous physical examination had revealed an injected pharnyx with multiple ulcerations. Laboratory findings on admission included a hematocrit of 25%; WBC of 13,500, with 66% mature polymorphonuclear leukocytes, 24% mature lymphocytes, and 4% nucleated red blood cells. Serum electrolytes were sodium, 138 mEq/liter; potassium, 5.6 mEq/liter; chloride, 105 mEq/liter; and carbon dioxide, 22 mM/liter. Diagnosis was hyperventilation syndrome. Postmortem findings were morphologically and serologically characteristic of acute herpetic hepatitis. The yellow-tan liver was dotted with circular hemorrhagic rings. The parenchyma within the rings was soft and necrotic. Hepatocytes bordering focal areas of necrosis and hemorrhage contained enlarged nuclei, many with Cowdry Type A inclusion bodies. Viral particles within hepatocytes had an electron dense core surrounded by both single and double membranes. Tissue homogenates produced partial cell destruction in human embryonic kidney 24 hr after inoculation; similar changes were seen in other cultures on the 4th day. The viral isolate from postmortem material was typed by neutralization using *Herpesvirus hominis* hyperimmune guinea pig sera. The specimen was then subtyped as Type I using specific sera. Studies with the median tissue culture infective dose of the maternal virus showed the 2-yr-old son had a neutralizing titer of 1:20 in subacute serum and 1:160 in 5-week convalescent serum. Only 2 other documented cases of *Herpesvirus hominis* in otherwise healthy adults are reported in the English literature; one of these was a 39-yr-old male and the other a young woman in the 28th week of pregnancy. Depressed immunoglobulin levels may contribute to the occurrence of this entity in the 3rd trimester of pregnancy. With the advent of effective chemotherapy (cytosine arabinoside), the diagnosis should be strongly considered in pregnant women with pharyngeal ulceration and systemic symptoms.

2326 DETECTION OF AUSTRALIA ANTIGEN IN LIVER BIOPSIES BY IMMUNOFLUORESCENCE. *(E.)*

Cerat, G.; Richer, G.; Viallet, A.; Cote, J.; Robert, J.; Turgeon, F. (St. Luke Hosp., Montreal, Canada). *Can. Med. Assoc. J.* 108(8):981-984, 1973.

A search for Australia antigen was made by immunofluorescence in 105 liver biopsies obtained from the same number of patients. No specific fluorescence was observed in 38 cases of acute viral hepatitis (19 of them seropositive for Australia antigen) or in 55 seronegative patients with various liver disorders including alcoholic hepatitis (9), micronodular cirrhosis (14), alcoholic hepatitis with cirrhosis (10), metastases to liver (4), nonspecific focal hepatitis (4) and hepatic steatosis (3), or in 8 seronegative patients with histologically normal livers. However, specific fluorescence was seen in 2 cases; in the single case of chronic aggressive hepatitis seropositive for Australia antigen and in 1 of 3 cases of chronic persistent hepatitis with Australia antigen-positive sera. The fluorescence observed was mainly intranuclear when cellular suspensions were used, but cytoplasmic fluorescence was more prominent when observations were made on cryostat sections. The finding of Australia antigen by immunofluorescence in liver

lls in chronic but not in acute forms of hepatitis
ropositive for Australia antigen is consistent
th the hypothesis that Australia antigen-positive
ute or chronic hepatitis may be an indication of
e cellular immune response of the host against
ver cells infected with hepatitis B virus.

27 IN VITRO TRANSFER OF CELL-MEDIATED IMMUNITY TO HEPATITIS B ANTIGEN WITH RNA.

.) Vyas, G. N.; Ibrahim, A. B.; Rao, K. R.;
hite, V. (Dept. Clin. Pathol. Lab. Med., Univ.
lifornia, San Francisco). *Nature* 247(5440):377-
3, 1974.

vitro transfer of cell-mediated immunity to
nimmune cells was demonstrated by inhibition of
gration in the presence of hepatitis B antigen
BAg), using RNA extracted from lymphoid tissue
Hartley guinea pigs immunized with HBAg. For
gration inhibition assays, 0.5 ml of medium con-
ining 7 x 10^7 peritoneal exudate cells from a
rmal guinea pig was incubated at 37 C for 30 min
th 0.5 ml solution of RNA from HBAg-immunized
imals (IRNA). The IRNA clearly and repeatedly
hibited migration of peritoneal macrophages in
e presence of HBAg. RNA from animals immunized
th complete Freund's adjuvant (NRNA) did not in-
bit migration in the presence of HBAg. Macrophage
gration in the absence of HBAg was unaffected by
eatment of cells with IRNA or NRNA. The ability
IRNA to transfer cellular immunity was destroyed
treatment with protease-free RNase. The results
ggest that experimental transfer of cell-mediated
munity to HBAg with IRNA is a specific phenomenon
duced by nondialyzable RNA extracts of lymphoid
gans of guinea pigs immunized against HBA.

28 EVIDENCE AGAINST RECESSIVE INHERITANCE OF SUSCEPTIBILITY TO THE CHRONIC CARRIER TE FOR HEPATITIS B ANTIGEN.

(E.) Vyas, G. N.
iv. California Sch. Med., San Francisco).
ure 248(5444):159-160, 1974.

hinese family consisting of 2 hepatitis B anti-
(HBAg) carrier parents and 3 children was tested
HBAg and anti-HBAg. HBAg was consistently de-
ted in the serum of both immigrant parents over
-month period. Clinical and biochemical results
ggested absence of liver abnormality in the par-
s, who were concluded to be asymptomatic chronic
riers. The 3 children were negative for HBAg
repeated testing of their sera by every method
luding radioimmunoassay. However, the 10-yr-
son had specific anti-HBAg with a titer of 256
hemagglutination assay. The 5-yr-old daughter
3-yr-old son had no antibodies. The fact that
e elder boy did not become a chronic carrier after
osure to HBAg but produced an immune response in
e form of antibody production is evidence that sus-
tibility to the chronic carrier state is not in-
ited as a simple autosomal recessive trait. A
ily clustering of HBAg-positive individuals is
e likely a function of increased opportunity
environmental exposure to the infectious agent.

2329 POSTNATAL CYTOMEGALOVIRUS HEPATITIS. AN AUTOPSY AND LIVER BIOPSY STUDY. *(E.)*

Henson, D. E.; Grimley, P. M.; Strano, A. J. (Natl. Cancer Inst., Bethesda, Md.). *Hum. Pathol.* 5(1):93-103, 1974.

Cytomegalovirus hepatitis was studied in 13 patients (aged 2-66 yr, mean 26.9 yr); 11 had died during disseminated cytomegalovirus infection and 2 had liver biopsies for suspected hepatitis. Of these 2 patients 1 was a 17-yr-old boy with acute lymphocytic leukemia and the other was a 41-yr-old woman with a myeloproliferative disorder. Histologically, inclusions were present in liver cells of all 3 lobular zones and less frequently in the vascular endothelium of the portal areas. Infected liver cells were seen in the cords, partially extruded into sinusoids, or within sinusoids where they were surrounded by inflammatory cells that formed small focal lesions. Once surrounded, infected cells degenerated into acidophilic bodies. In portal areas in which inclusions were seen there was a variable infiltration of acute and chronic inflammatory cells. The number of infected cells varied considerably in the livers from different patients. In the 2 patients with liver biopsies, SGOT, SGPT, and alkaline phosphatase activities were transiently increased. Serological studies in these 2 patients showed high titers of cytomegalovirus complement-fixing antibody. The results indicate that cytomegalovirus hepatitis is characterized by a focal mononuclear cell infiltration in the lobules and a pleomorphic cell infiltration in the portal areas. The lesions associated with virus-infected cells are not diagnostic except when intranuclear inclusions are seen. The histological lesions of biopsy proved cytomegalovirus hepatitis resemble the changes seen in livers of patients dying with hepatic involvement during disseminated infection.

2330 DISSEMINATED INTRAVASCULAR COAGULATION ASSOCIATED WITH HEPATITIS IN LATE PREGNANCY. *(E.)*

Jones, C. T. A.; Birch, C. R.; Poller, L.; Dymock, I. W. (Univ. Hosp. South Manchester, England). *Gut* 14(11):891-894, 1973.

A 36-yr-old patient with viral hepatitis in the 3rd trimester of pregnancy is described. She developed grade II-III hepatic coma in the postpartum period which was associated with evidence of intravascular coagulation, including depression of fibrogen levels, absence of normal puerperal elevation of the platelet count, and gross increase in fibrin breakdown products (307-1249 μg/ml). Serum bilirubin was 9.7 mg%; serum alkaline phosphatase, 41 King-Armstrong U/100 ml; and SGPT, 69 U/ml. Following therapy with heparain (1000-1500 U/hr) and fresh frozen plasma (1 U every 12 hr), the patient improved dramatically. At time of discharge on the 15th day after delivery she was asymptomatic. The infant was well throughout and at 6 months continues to have normal liver function tests with a negative HBAg test. It is suggested that intravascular coagulation in this case followed release of tissue thromboplastins during hepatocellular necrosis with a component contribution from the placental site.

2331 IMMUNOLOGICAL AND ELECTRON MICROSCOPE DETECTION OF AUSTRALIA ANTIGEN (HEPATITIS B ANTIGEN) IN STOOL AND URINE SAMPLES FROM PATIENTS WITH VIRAL HEPATITIS B. *(Ger.)* Sonnabend, W.; Kistler, G. S.; Krech, U.; Jung, M.; Uberschlag, M. L. (St. Gallen Cantonal Inst. Bacteriol., Switzerland). *Schweiz. Med. Wochenschr.* 102(42):1503-1508, 1972.

A modified immunodiffusion technique was used to test for Australia antigen (AuAg) in blood, urine, and stool samples from 86 Au Ag-positive patients with acute serum hepatitis, 12 Au Ag-positive patients with chronic persistent or chronic aggressive hepatitis, and 4 Au Ag-positive patients with cirrhosis and in urine and stool samples from controls with acute gastrointestinal infections or acute or chronic urinary infections. Among patients with acute or chronic urinary infections. Among patients with acute serum hepatitis, Au Ag was detected in 67 of 99 stool specimens (67.7%) and in 32 of 75 urine samples (42.7%). Au Ag was also detected in 6 of 13 stool samples (46.1%) and 3 of 6 urine specimens from patients with chronic hepatitis, and in 3 of 4 stool samples and 1 of 2 urine specimens from patients with cirrhosis. Au Ag was not found in any urine or stool samples from controls. Electron microscope examination of precipitation lines from immunodiffusion plates obtained from 13 stool and 9 urine specimens revealed the presence of immune complexes consisting almost entirely of particles averaging 200 Å in diameter with a few having diameters of about 300 Å. No Dane particles were found. It is concluded that these immune complexes are identical to Au Ag present in blood samples. Until completely reliable methods are developed to detect the infectious agent in a body fluid, it should be assumed that blood, urine, or stool samples containing Au Ag are potentially infectious.

Chronic Hepatitis

344 CHRONIC HEPATITIS IN CHILDREN. *(E.)*
Alagille, D.; Gautier, M.; Herouin, C.;
adchouel, M. (Parrot Hosp., Bicetre, France).
cta Paediatr. Scand. 62(6):566-570, 1973.

istologic findings showed only 16 cases of chronic
epatitis among 35 children originally diagnosed as
aving the disease. Of the 16 cases, 3 had per-
istent nonaggressive hepatitis, 6 chronic active
epatitis of mild intensity (type *a*), and 7 chronic
ggressive hepatitis of severe intensity (type *b*).
n chronic persistent hepatitis, lobular architec-
ure was preserved and portal infiltration and
ortal fibrosis were moderate. There was no piece-
eal necrosis. Type 2 *a* aggressive hepatitis was
ifferentiated on the basis of moderate piecemeal
ecrosis with unclear lobular-portal junction.
ortal fibrosis and inflammatory portal infiltra-
ion were moderate; lobular architecture was nor-
al or little changed. Type 2 *b* aggressive hepatitis
as characterized by profound changes in lobular
rchitecture and severe piecemeal necrosis, portal
nflammatory infiltration, and portal fibrosis. As
reviously reported, there was a prevalence of fe-
ales with chronic hepatitis (12 girls *versus* 4
oys). Pooled data show that incidence increases
rom 2 to 15 yr. Only 4 of the 16 children had a
istory of acute hepatitis; and only 4 of 9 tested
ere positive for Australia antigen. In contrast
o the benign evolution of persistent nonactive
epatitis, chronic aggressive hepatitis shows acute
apid evolution. Control studies demonstrate a
onger survival under corticosteroid therapy, pro-
ided treatment is given during the 1st year of the
isease.

45 A CASE OF ACTIVE CHRONIC HEPATITIS WITH
PAINLESS EROSIVE ARTHRITIS. *(E.)*
rnardo, D. E.; Vernon-Roberts, B.; Currey, H. L.
(Queen Mary's Hosp., London, England). *Gut*
(10):800-804, 1973.

thritis appeared in a 21-yr-old girl 4 yr after
e diagnosis of active chronic hepatitis with
rrhosis. Neither Australia antigen nor epidemic
epatitis-associated Milan antigen was present in
r serum, and tests for serum DNA antibodies and
mplement degradation products were negative.
wever, serial determinations of the C_3 and CH_{50}
actions of serum complement have given persistently
w values. The arthropathy was limited to small
ints of the hands and feet; despite marked soft
ssue swelling, the range of movements was full
d painless. Radiographs of the affected joints
owed destructive and erosive changes with some
riosteal new bone formation. Open biopsy, car-
ed out on the right middle proximal interphalan-
al joint, showed a grossly thickened and edematous
novium. Light microscopy revealed abundant
brinoid material on and within the surface synovial
yer, replacing it in many cases. Electron micro-
opy showed abundant noncollagenous dense fila-
ntous material and scattered collagen fibers in
e surface fibrinoid. Immunofluorescence revealed
undance of IgG in the surface fibrinoid together with small amounts of IgM and a moderate amount of C_3 complement. The arthritis persisted for 10 months, then resolved spontaneously. The synovial appearance would suggest the deposition of immune complexes during the acute arthritis. However, the failure to detect complement degradation products after the arthritis had settled and the consistently subnormal serumcomplement levels indicate impaired hepatic synthesis at the present time, rather than increased consumption of complement.

2346 IMPORTANCE OF THE PROGNOSIS IN THE STUDY OF CHRONIC HEPATITIS: RESULTS OBTAINED WITH IMMUNOSUPPRESSANTS. *(Sp.)* Aguilar Reina, J.; de la Santa, J.; Andreu Kern, F. (Virgen del Rocio Munic. Sanit., Sevilla, Spain). *Rev. Esp. Enferm. Apar. Dig.* 41(3):243-254, 1973.

Clinical, laboratory, and radiological findings were studied in 23 patients (16 men and 7 women; mean age 35.3 yr) with chronic hepatitis to determine which factors might be useful in establishing a prognosis. No relation was found between the later course of the hepatitis and age, sex, a history of acute hepatitis, or the severity of acute hepatitis. In 3 of the 10 patients who eventually developed aggressive hepatitis or cirrhosis there was jaundice and diseases or habits which contributed to metabolic changes (diabetes, alcoholism, postgastrectomy steatorrhea). Liver biopsies proved to be the most useful tool for establishing a prognosis, the most significant changes being piece-meal necrosis, loss of the outlines of hepatic lobules, and parenchymal fibrosis. The course was downhill in all cases in which biopsy findings were consistent with chronic aggressive hepatitis. All patients whose condition later deteriorated initially had significant increases in IgG levels which were associated with increased IgM levels in 6 cases and increased IgA levels in 2. Australia antigen, present initially in 3 patients, later became negative. Although laparoscopy was useful in daignosing cirrhosis, which could not be detected by biopsy in all cases, it was not helpful in establishing a prognosis. Except for the lupus erythematosus phenomenon, which was found in 1 patient, none of the other parameters studied (liver function tests, antinuclear factor, rheumatoid factor, antithyroid antibodies, complement (C-3), Mantoux test, BSP clearance, liver blood flow, scintillation scanning) contributed to the establishment of a prognosis. Therapy consisted of lipotropic agents (unspecified) in 14 patients with initially normal immunoglobulin levels and azathioprine (100 mg/day for 1-3 yr) in 7 patients with initially increased immunoglobulin levels. Azathioprine had no favorable effect on the course of chronic hepatitis which would justify its use.

2347 HISTOCOMPATIBILITY ANTIGENS IN LIVER DISEASE. *(Ger.)* Freudenberg, J.; Erdmann, K.; Meyer zum Buschenfelde, K. H.; Forster, E.; Berger, J. (2nd Med. Clin., Johannes Gutenberg

Univ., Mainz, Germany). *Klin. Wochenschr.* 51(21):1075-1076, 1973.

Histocompatibility antigens (HL-A) were typed in 124 patients with acute hepatitis, 19 with chronic persistent hepatitis, 56 with chronic aggressive hepatitis, 42 with cirrhosis, 37 with metabolic diseases of the liver and in 83 normal controls. Among the 56 patients with chronic aggressive hepatitis, HL-A1 was found in 30 (54%) and HL-A8 in 34 (61%). The incidence of these antigens is significantly greater than among the controls (18% and 17%, resp.). These findings suggest that the HL-A locus on the chromosome is associated with certain immunological reactions. Therefore, HL-A typing can give information about genetic predisposition to and the pathogenesis of diseases.

2348 TREATMENT OF CHRONIC LIVER DISEASE. *(Ger.)*

Hilt, G.; Reitmeier, H. (Bayerwald Sanit., Cham-Windischbergerdorf, Germany). *Z. Allgemeinmed.* 49(7):327-329, 1973.

A comparison was made of the effects of 5% fructose infusions and Metabolan, a preparation containing xanthinol niacinate and B vitamins including biotin, on liver function tests, hepatosplenomegaly, and subjective symptoms in 84 patients with chronic liver disease. These patients consisted of 14 with steatotic hepatitis, 32 with chronic persistent hepatitis, 14 with chronic aggressive hepatitis, and 24 with manifest cirrhosis. Half of these patients received infusions of Metabolan 3 times a week in 500 ml 5% fructose with doses increasing to 3000 mg xanthinol niacinate; 2 Metabolan tablets were administered 3 times a day on the days between infusions. The other half of these patients received infusions of 5% fructose. Metabolan was significantly more effective than 5% fructose in reducing SGOT, SGPT, and serum glutamate dehydrogenase activities. It also reduced the volume of the liver and caused improvement in general well-being and symptoms such as meteorism, fullness, and fatigue. Although most patients initially complained that Metabolan caused flushing, pruritis, headaches, and anorexia, these symptoms usually decreased in intensity or disappeared. Metabolan did cause an increase in blood sugar levels in a diabetic with cirrhosis; it became necessary to increase the dose of insulin given to this patient. However, blood sugar levels decreased again when Metabolan infusions were replaced by p.o. administration of the drug. These findings suggest that Metabolan prevents hepatic necrosis and promotes regeneration of connective tissue.

2349 D-PENICILLAMINE THERAPY IN LIVER DISEASE: PRELIMINARY RESULTS FROM 44 CASES. *(Ger.)*

Alexander, M.; Wille, G. (Westend Clin., Free Univ., Berlin, Germany). *Munch. Med. Wochenschr.* 116(5): 211-216, 1974.

D-Penicillamine was given to 10 patients with protracted courses of acute viral hepatitis and to 34 with chronic aggressive hepatitis in various stages of development. Therapy was begun with 300 mg/day of D-penicillamine, and doses were gradually increased to 600-1800 mg/day. Patients also received supplements of vitamin B_6 (120-300 mg/day) and metals (salts of Fe, Co, Mg, Mn, and Zn once a week). Administration of D-penicillamine for 4-13 months to 15 patients with chronic aggressive hepatitis and incipient fibrosis caused definite improvement in 6, slight improvement in 3, and stabilization of fibrosis in 3. Therapy was discontinued in 3 cases. Of 10 patients with chronic aggressive hepatitis and histological evidence of cirrhotic changes, 4 improved, 4 showed no histological changes, and therapy was discontinued in 3 cases. Among 9 patients with active cirrhosis, 2 failed to improve and 6 had to stop taking D-penicillamine because of thrombocytopenia; the remaining patient has not been followed long enough for results to be evaluated. Of 10 patients with protracted courses of acute viral hepatitis, 8 improved significantly and 1 developed cirrhosis; no final histological follow-up was made on the remaining patient. In addition to thrombocytopenia, side effects included taste disturbances (1 patient) and allergies (4 patients). Two of the 4 patients with allergies were able to continue taking D-penicillamine after therapy had been discontinued by combining D-penicillamine with prednisolone. Although D-penicillamine appears to be effective in the treatment of protracted viral hepatitis and chronic aggressive hepatitis with incipient degenerative changes, it has little effect on active cirrhosis.

2350 TREATMENT OF CHRONIC LIVER DISEASE WITH D-PENICILLAMINE. *(Ger.)*

Wildhirt, E. (Munic. Hosp., Kassel, Germany). *Munch. Med. Wochenschr.* 116(5):217-220, 1974.

D-Penicillamine was used to treat 86 patients (54 men and 32 women) with chronic liver disease who had been treated unsuccessfully with conventional liver therapy, corticosteroids, or immunosuppressants for at least 3-6 months. These consisted of 60 patients with chronic aggressive hepatitis, 12 with protracted postacute hepatitis, 11 with posthepatitic or postnecrotic cirrhosis, and 3 with Wilson's disease. D-Penicillamine was instituted at a dose of 300 mg/day, and the dose was then increased to 1800 mg/day over a 4-week period. All patients also received vitamin B_6 (300 mg 3 times a week), and iron and trace metals were administered to all except those with Wilson's disease. After normalization of liver function tests and significant improvements in histological findings, the dose was reduced to 900-1200 mg/day. This dose was administered for 4 months after complete normalization or histological recovery to prevent rebound phenomenon. Therapy was unsuccessful in 26 of these 78 patients (32.5%): 12 failed to improve after at least 6 months and the drug had to be discontinued in 2 patients whose conditions became worse and 12 patients who developed side effects. Four patients died of other causes during treatment. Analysis of the results of liver function tests in the remaining 48 patients showed complete normalization in 30 (38%), significant improvement in 14 (18%), and no change in 4 (5%). Based on the results of follow-up biopsies performed on 39 of these patients, D-penicil-

mine gave very good results in 17, good results in
, and had no effect on 2. These results are
ch better than those previously obtained in 25 pa-
ents with long-term azathioprine therapy: inflam-
tory changes in the liver regressed in only 5 pa-
ents treated with this agent. D-Penicillamine pro-
ced side effects in 21.5% of the patients. Thera-
had to be discontinued in 12 patients (15%) be-
use of proteinuria (5 cases), allergy (4), and 1
se each of severe nausea, thrombocytopenia, and
ranulocytosis. Reversible side effects occurred
5 patients (6.5%) and consisted of allergy (2
ses), arthralgia (2), and thrombocytopenia (1).

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

54 PLASMA FACTOR X_a-INHIBITORY ACTIVITY IN
ALCOHOLIC LIVER DISEASE AND THE EFFECT OF
PARIN. *(E.)* Gavrilis, P.; Lerner, R. G.; Gold-
ein, R. (New York Med. Coll., N.Y.). *Thromb. Res.*
2):335-343, 1974.

ctor X_a-inhibitor (X_a-I) activity was measured in
patients with alcoholic liver disease and found
be more than 3 standard deviations below normal
14 patients. When trace amounts of heparin were
ded to these plasmas, the X_a-I activity was poten-
ated to the same level as normal plasma with
parin added. This suggests that X_a-I is actually
esent in alcoholic liver disease, but has less
an normal activity. Possible explanations such
the lack of endogenous heparin or the presence
an inhibitor are discussed. One explanation might
that patients with alcoholic liver disease have
low X_a-I level on direct kinetic analysis which
subsequently masked by the marked rate increase
used by adding heparin. A second explanation
ght be that there is an abnormal X_a-I molecule
ich has less than normal X_a-I activity but can be
tentiated to normal inhibitor levels by heparin.
hird explanation might be that normal individuals
ve a small amount of endogenous heparin which is
cking in patients with liver disease, and normal
-I activity depends upon its presence. Finally,
inhibitor might be present in patients with
ver disease.

55 FATTY LIVER PERSISTING FOR UP TO 33 YEARS.
A FOLLOW-UP OF THE IVERSEN/ROHOLM LIVER
OPSY METHOD. *(E.)* Hilden, M.; Juhl, E.; Thomsen,
C.; Christoffersen, P. (Bispebjerg Hosp., Copen-
gen, Denmark). *Acta Med. Scand.* 194(6):485-489,
73.

Re-evaluation of 890 consecutive liver biopsy specimens from the period 1938-1956 has been carried out and fatty liver was diagnosed in 59 cases. A follow-up examination was performed on 58 of these patients, their time of observation in respect to long-time prognosis of fatty liver varying from 16-33 yr. Half of them were alcoholics (defined as ethanol intake above 50 g/day for 5 yr). Evaluation of the liver was done on the basis of microscopy from repeated biopsy or autopsy (18 cases), on postmortem gross examination (19 cases), on clinical and laboratory findings (4 cases) or on death certificate (17 cases). In the follow-up period, cirrhosis of the liver was diagnosed in only 2 patients, 1 an alcoholic. A certain degree of fatty liver was shown in nearly all cases in which histology had been performed. These results support the hypothesis that steatosis and cirrhosis represent the various forms of liver response to alcohol, rather than coherent stages in the development of alcoholic liver damage. Thus, factors other than alcohol abuse must be important in the development of cirrhosis.

2356 FACTORS DETERMINING LIVER DAMAGE IN CHRONIC ALCOHOLICS. *(E.)* Eghoje, K. N.; Juhl, E. (Community Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 8(6):505-512, 1973.

Liver biopsies from 330 Danish chronic alcoholics showed cirrhosis in 60 cases and normal liver morphology in 29. Patients with cirrhosis were significantly older (average age, 46 yr), but the 2 groups did not differ with respect to sex, occupation, schooling, trade, and taxable income. Daily alcohol consumption averaged 181 g among patients with cirrhosis and 169 g among those with normal liver morphology. Average duration of alcohol abuse was 23 yr for cirrhotic patients compared with 17 yr for those with normal liver morphology. Significantly more patients with cirrhosis had a daily ethanol intake exceeding 125 g and significantly more had abused alcohol for more than 10 yr. The 2 groups did not differ in drinking habits: more than 90% of all patients preferred beer, alone or in combination with acquavit. All biochemical liver tests differed significantly in the 2 groups, as did the frequencies of symptoms and signs other than alcoholic dementia. This study suggests that the development of cirrhosis in chronic alcoholics is related to the extent and duration of alcohol abuse.

2357 REVERSIBILITY OF BIOLOGICAL SIGNS OF CIRRHOSIS IN THE CHRONIC ALCOHOLIC AFTER ABSTINENCE FROM ALCOHOL. *(Fr.)* Lamy, J.; Aron, E.; Lamy, J.; Martin, J. C.; Weill, J. (Fac. Med., Tours, France). *Clin. Chim. Acta* 49(2):189-193, 1973.

Immunoglobulins were separated by polyacrylamide gel electrophoresis, and serum transferrin and IgA concentrations were measured by radial immunodiffusion in 83 chronic alcoholics with no clinical evidence of cirrhosis who had stopped drinking for at least 1 yr. The values obtained were compared with those from 43 chronic alcoholics who continued to drink. Serum IgA levels decreased significantly in subjects who abstained from alcohol but increased significantly in those who cintinued drinking. Among the patients who abstained, a negative correlation was found between the decrease in IgA concentration and the initial IgA concentration. Abstinence did not produce a significant change in serum transferrin levels. The increase or decrease in IgA levels in chronic alcoholics may be correlated with inflammatory infiltration of the hepatic mesenchyma.

2358 MALLORY'S ('ALCOHOLIC') HYALINE IN PRIMARY BILIARY CIRRHOSIS. *(E.)* MacSween, R. N. M. (Western Inform., Glasgow, Scotland). *J. Clin. Pathol.* 26(5):340-342, 1973.

Mallory's hyaline was present in hepatocytes of 18 (26%) of 70 patients with primary biliary cirrhosis. None of these 18 patients had a documented history of alcohol abuse. The hyaline was noted in biopsy material for 12 patients and in autopsy material for 4. In 1 case it was present in both autopsy material and in a biopsy taken 6 yr earlier and in 1 case hyaline was identified in postmortem liver, there having been no earlier biopsy. The distribution of the hyaline was adjacent to portal tracts and connective tissue septa, and corresponded to the distributional pattern of peripheral cholestasis which is seen in primary biliary cirrhosis. However, none of the hepatocytes contained both retained bile and hyaline. In 5 cases hyaline deposits were present in considerable amounts, but in the remainder the deposits were scanty to moderate. In the 1 patient in whom hyaline was seen in both biopsy and autopsy material, greater amounts were present at autopsy. The presence of hyaline did not correlate with any other clinical or biochemical parameter of the disease. Recent studies have indicated that hyaline deposits belong to the category of contractile cytoplasmic filaments. The present findings further emphasize that they are probably not pathognomonic of alcohol abuse. However, the nature of this particular reaction of the hepatocyte to injury in a number of different diseases remains to be elucidated.

2359 AUGMENTED RELEASE OF HEPATIC TRIGLYCERIDES WITH ANABOLIC STEROIDS ON PATIENTS WITH FATTY LIVER. *(E.)* Mendenhall, C. L. (VA Hosp., Cincinnati, Ohio). *Am. J. Dig. Dis.* 19(2):122-126, 1974.

Hepatic triglyceride mobilization before and after treatment with norethandrolone (100 mg i.m.) was measured, using hepatic vein catherization, in 7 patients with fatty liver. An additional 2 patients were injected with isotonic saline in lieu of the anabolic steroid. Norethandrolone markedly increased hepatic triglyceride release over mean pretreatment and control values (22.7 mg/min). The effect was obvious in 6 of the 7 cases by 4 hr and was maximal (1616 mg/min) in all cases by 10 hr. The rate of triglyceride mobilization then decreased, returning to pretreatment values by 24 hr. In 4 patients for whom liver biopsy material was available, pretreatment hepatic venous blood resembled liver tissue in triglyceride composition. Norethandrolone increased the saturated fatty acids, principally palmitate and stearate, at the expense of oleate. An increase was also observed in medium-chain triglyceride fatty acids. It is concluded that anabolic steroids accelerate hepatic triglyceride removal through increased lipoprotein release and/or synthesis.

2360 EFFECTS OF PHENOBARBITAL ADMINISTRATION ON RATES OF ETHANOL CLEARANCE AND ON ETHANOL-OXIDIZING ENZYMES IN MAN. *(E.)* Mezey, E.; Robles, E. A. (Baltimore City Hosp., Md.). *Gastroenterology* 66(2):248-253, 1974.

The effects of phenobarbital administration on rates of ethanol disappearance from the blood and on the hepatic activities of the ethanol-oxidizing enzymes were determined in 4 male chronic alcoholic patients (aged 32-43 yr) without significant clinical evidence of liver disease. Phenobarbital (240 mg/day, p.o., in 4 divided doses for 6 consecutive days) resulted in significant increases, in the rates of ethanol disappearance from the blood (from 15.7 to 20.1 mg/100 ml serum/hr) and in the concentration of protein/g of liver wet weight (from 130.2 to 182.7 mg/g); however, no changes were observed in the activities of either alcohol dehydrogenase or the nicotinamide adenine dinucleotide phosphate-dependent ethanol-oxidizing system determined in liver homogenates. On the other hand, the urinary excretion of D-glucaric acid, an index of hepatic enzyme induction, was increased (from 13.9 to 58.7 μM/day). While this study demonstrates an enhancement of ethanol clearance from the blood after phenobarbital administration, the mechanism for this enhancement remains uncertain.

LIVER AND BILIARY TRACT

Cirrhosis

53 LONG-TERM RESULTS FROM TREATING CIRRHOSIS BY LIGATING THE HEPATIC ARTERY. (25 CASES).
.) Leger, L.; Albot, G.; Cachin, M.; Lemaigre,
; Blondel, P. (Cochin Hosp., Paris, France).
n Chir. 69(5):321-326, 1973.

tween 1951 and 1963, the common hepatic artery was
gated in 25 patients (10 women and 15 men, aged
-67 yr) with severe cirrhosis. Ascites was pre-
nt in 16, jaundice in 2, and 10 presented with gas-
ointestinal bleeding. Of these 25 patients, 11
ed within 2 months after surgery and 6 in satis-
ctory condition were lost to follow-up after 20
s to 3 yr. Of the 8 survivors, 6 died after 9
nths to 11 yr, and 2 are still alive 13 and 15 yr
er surgery. An analysis of the findings in 5
ients who survived for more than 5 yr reveals
t ligation of the hepatic artery does not cause
asting reduction in portal pressure and has no
nificant effect on ascites or gastrointestinal
eeding. This procedure did improve liver function
ts and caused stabilization of sclerosis, regres-
n of inflammatory infiltrates, and hyperplastic
eneration of cirrhotic nodules. Steatosis, the
nificance of which is unknown, appeared in 3 of
4 patients whose histological findings are
cribed. These long-term findings suggest that
r results obtained with ligation of the hepatic
ery cannot be attributed entirely to the method
are also due to poor selection of candidates
this procedure. These patients were in poor
eral condition before surgery and currently used
retics, protease inhibitors, and ε-aminocaproic
d were not available.

4 PAROTID HYPERTROPHY IN CIRRHOSIS. I. CLINICAL AND FUNCTIONAL STUDY. *(Sp.)* Rod-
o Gomez, J. M.; Aparisi Quereda, L.; Palao Esteve,
Guix Garcia, J.; Serra Desfilis, M. A.; Benages
tinez, A.; Garcia-Conde Gomez, F. J. (Fac. Med.,
encia, Spain). *Rev. Esp. Enferm. Apar. Dig.*
527-538, 1973.

nical evidence of parotid hypertrophy was detected
the criteria of Sposito and Wolfe in 20 of 68
ients with cirrhosis (29%). These consisted of
patients with grade I hypertrophy, 6 with grade
and 3 with grade III. Parotid hypertrophy was
sent in 9 of 27 patients with alcoholic cirrho-
and in 14 of 41 with other forms; this difference is not significant. Of the 20 patients with cirrhosis and parotid hypertrophy, 8 had body weights greater than their ideal weight. These 8 patients had a significantly greater incidence of more pronounced parotid hypertrophy than the 12 patients who had body weights lower than their ideal weight, suggesting that apparent hypertrophy in overweight patients is really due to deposits of fat. No correlations were found between the extent of parotid hypertrophy and plasma albumin levels, ascites, or hepatosplenomegaly. The correlation between the extent of parotid hypertrophy and alcoholism was of borderline significance. A comparison of the parotid saliva output, the pH of the saliva, and salivary amylase activity was made under basal conditions and after stimulation with 2% citric acid in 16 patients with cirrhosis and parotid hypertrophy and 17 normal controls. No significant differences were found between the 2 groups in any of these 3 parameters or between these parameters and the extent of hypertrophy.

2365 PAROTID HYPERTROPHY IN CIRRHOSIS. II. MORPHOLOGICAL, HISTOCHEMICAL, AND ULTRASTRUCTURAL STUDY. *(Sp.)* Rodrigo Gomez, J. M.; Peydro Olaya, A.; Llombart Bosch, A.; Aparisi Quereda, L.; Serra Desfilis, M. A.; Guix Garcia, J.; Palao Esteve, J.; Benages Martinez, A.; Garcia-Conde Gomez, F. J. (Fac. Med., Valencia, Spain). *Rev. Esp. Enferm. Apar. Dig.* 41(7):751-770, 1973.

Histological, histochemical, and ultrastructural examinations were performed on biopsied material from the parotid glands of 20 patients with cirrhosis and clinical parotid hypertrophy as determined by the criteria of Sposito and Wolfe. Sialographic examinations, performed on 15 of these patients, were completely normal in 9 cases except for the apparent increase in size. In the remaining 6 cases there was massive lobular filling and ductal angles greater than 90°. None of these patients had parotid lithiasis or sialectasia. Except for microlithiasis in the striated ducts in one case, histological findings were essentially normal. Although no evidence of increased mitosis was found, acinar cells were hypertrophied and filled with secretion granules, and moderate fat infiltration was observed. Staining with Sudan III showed marked degeneration of parenchymal fat and the presence of small vacuoles of fat in the protoplasm in all parts of the gland. Electron microscopy revealed that these vacuoles sometimes produced deformations in the nuclear membrane. Secretion of the mucus type was more abundant in parotid acinar cells of patients with cirrhosis than in those of 3 normal controls. Histochemical studies of a variety of enzymes showed a radically different pattern of activities from that in experimental sialoadenosis induced in rats with isoproterenol. This suggests that experimental sialoadenosis is not a good model for studying asymptomatic parotid hypertrophy in man.

2366 CRUVEILHIER-BAUMGARTEN DISEASE ASSOCIATED WITH CIRRHOSIS. *(Ger.)* Dux, E.; Laszlo, A. (Med. Univ., Szeged, Hungary). *Monatsschr. Kinderheilk.* 121(3):98-100, 1973.

A 9.5-yr-old boy with a history of hepatitis developed ascites preceded by rapidly increasing signs of venous dilatation on the abdominal wall. The patient's condition deteriorated rapidly with vomiting, increaingly pathological liver function tests, and a large subcutaneous hemorrhage on the abdomen near the genitals. Abdominal paracentesis yielded 9 liters of yellow fluid. The patient developed severe pains in the lower abdomen 9 hr after surgery and collapsed and died despite administration of transfusions, infusions, and drugs to increase his blood pressure. Autopsy revealed a persistent, dilated umbilical vein which opened into the portal vein. Large abdominal veins were dilated and sclerotic due to portal hypertension, and massive enlargement of the spleen, ascites (4.5 liters), and congestion of the gastric and duodenal mucosa could be traced to portal congestion. Other findings included postnecrotic cirrhosis, esophageal varices, and 400 ml of fresh blood in the stomach and duodenum. The immediate cause of death is considered to be ruptured esophageal varices although the site of the rupture could not be located. Despite the presence of severe cirrhosis, this patient is diagnosed as having Cruveilhier-Baumgarten's disease, rather than Cruveilhier-Baumgarten's syndrome, because of the persistent umbilical vein. The cirrhosis was so severe that it could not be determined whether it had been preceded by hepatic hypoplasia. However, portal hypertension must have been present before obliteration of the umbilical vein occurred.

2367 CHANGES IN SOME PARAMETERS OF CONNECTIVE TISSUE METABOLISM IN CIRRHOSIS. *(Cz.)* Kuzela, L.; Horky, J. (Inst. Clin. Exp. Med., Prague, Czechoslovakia). *Cesk. Gastroenterol. Vyz.* 27(4): 217-223, 1973.

Connective tissue metabolism was investigated in the livers of 15 patients with cirrhosis and 13 normal controls, and these findings were compared with those obtained in Wistar rats with cirrhosis induced by carbon tetrachloride (1 ml/kg diluted 1:1 with olive oil given twice a day for 10 days) and in untreated controls. Statistically significant increases were found in the contents of hydroxyproline in both total and insoluble collagen fractions obtained from the livers of rats with cirrhosis. The content of hydroxyproline in insoluble collagen was also significantly increased in liver biopsies from patients with cirrhosis, and the absolute quantity of hydroxyproline in this fraction was somewhat larger than that in rats with cirrhosis. This is due partly to the greater degree of regeneration in the human livers and partly to species differences in the content of connective tissue in the liver. Although serum concentrations of total hydroxyproline were moderately increased in 9 cirrhotics, the difference between cirrhotics and controls was not statistically significant. With one exception, 24-hr excretion of acid mucopolysaccharides in the urine was not increased in patients with cirrhosis; values varied considerably when determinations were performed on several successive days. These findings in cirrhotics, together with others previously reported in the literature, are similar to those which occur in kwashiorkor. It is suggested that hepatocytes become malnourished in cirrhosis because of the proliferation of connective tissue, particularly in Disse's spaces where the supply of nutrients to the sinusoids becomes difficult. Thus, the hepatocytes are functionally less efficient and become very vulnerable to various toxic substances which the normal liver is able to eliminate rapidly.

2368 PORTAL-SYSTEMIC SHUNT IN HEPATIC CIRRHOSIS: DOES THE TYPE OF SHUNT DECISIVELY INFLUENCE THE CLINICAL RESULT? *(E.)* Bismuth, H.; Franco, D.; Hepp, J. (Hospital Paul-Brousse, Villejuif, France). *Ann. Surg.* 179(2):209-218, 1974.

Three different shunt techniques were studied: total direct portal-systemic shunt by end-to-side, or large-stoma side-to-side, porta-caval anastomosis in 25 patients; partial direct portal-systemic shunt by small-stoma side-to-side portacaval anastomosis in 23 patients; and central splenorenal anastomosis in 72 patients. The mean age of the patients was 50 yr, the range was 21 to 74. Alcholic cirrhosis was the best represented cause; the others included postnecrotic, primary biliary, and hemochromatosis. Of the 3 portal-systemic shunt procedures used, total direct portacaval anastomosis produced the greatest fall in portal pressure (14.6 mm Hg), the lowest post-shunt portal pressure (11.5 mm Hg), and a postshunt portal-caval pressure gradient of 3.4 mm Hg. Partial direct portacaval anastomosis lowered the portal pressure by 9.6 mm Hg to 14.4 mm Hg, and maintained the highest portal-caval pressure gradient 7.2 mm Hg. Splenorenal anastomosis gave a postshunt splenic vein pressure of 15.1 mm Hg; it left a splenorenal pressure gradient of 1.8 mm Hg. After small-stoma side-to-side portacaval anastomosis diversion of portal blood was partial in all the cases studied. After splenorenal anastomosis, 2 types of hemodynamic patterns were observed: partial diversion of portal blood and total diversion of portal blood. Thirty patients (25%) died, 2 during the first 60 postoperative days. Five-year survival was 65.9% for the whole series: 69.7% for total portacaval anastomosis; 65.8% for partial postacaval anastomosis; and 65.4% for splenorenal anastomosis. The principal nonimmediate cause of death was hepatocellular failure. The group in which hepatocellular failure was most lethal was the splenorenal anastomos

oup, in which it accounted for 70.6% of the deaths.
deaths were due to recurrent bleeding. Patients
er 60 had a slightly better survival rate than
tients under 60. Bleeding recurred in 5 patients,
l belonging to the splenorenal anastomosis group.
entgenographic examination by barium swallow 15
ys after operation in 86 patients revealed dis-
pearance of the esophagogastric varices in 65,
minution in 18, and no change in 3. Hepatic
cephalopathy developed in 14 patients; the severity
encephalopathy did not vary with shunt type. No
gnificant differences were found between the 3
unt types as regards postoperative mortality,
ng-term survival, recurrence of gastrointestinal
morrhage, persistence of esophagoagastric varices,
occurrence of hepatic encephalopathy.

59 LIVER BIOPSY FINDINGS IN CHILDREN WITH OBLITERATIVE PORTAL HYPERTENSION. *(E.)*

ister, P.; Engert, J. (Dept. Pathol., Univ. Munich,
rmany). *Beitr. Pathol.* 149(3):307-310, 1973.

ntralobular hepatic changes similar to those fre-
ently seen in adults with cardiac congestion were
served in 8 consecutive cases of children with
rtal vein thrombosis, unassociated with hepatic
sions compatible with intrahepatic block or
idence of posthepatic block. The 8 cases showed
ither fibrosis with destruction of hepatic archi-
cture, nor changes of the intrahepatic portal vein
anches or signs of venocclusive disease as possible
rphological correlates of portal hypertension caused
liver disease. In all of these 8 cases, peculiar
ntralobular perivenous changes were found. The
llagen fibers could well be demonstrated by van
eson stains. Most impressive were the increased
mbers and calibers of fibrillary structures after
lver impregnation. Long-term studies are needed to
parate late changes after primary portal vein
rombosis with secondary hepatic fibrosis and
literation of intrahepatic portal vein from primary,
e., congenital hepatic fibrosis with hypoplasia
intrahepatic portal vein branches and secondary
rtal vein thrombosis after portal hypertension.

0 TREATMENT OF EXTRAHEPATIC OBSTRUCTION OF THE PORTAL VEIN SYSTEM. *(E.)* Nielsen,

V.; Malmstrom, J.; Pagel, J.; Efsen, F. (Rigs-
p., Copenhagen, Denmark). *Scand. J. Gastroenterol.*
):599-604, 1973.

treatment of 7 patients with portal hypertension
sed by extrahepatic obstruction of the portal vein
described. Six of the patients presented gastro-
estinal bleeding from esophageal or fundic vari-
ities. All patients had a normal liver function,
in no case was ascites found. On admission,
enoportography was performed. There were 4
ales and 3 males. Their ages ranged from 8 to
yr. The splenic pressure (mm Hg) ranged from 15
34. The site of the obstruction was V. portae
all 7 patients and 2 patients also had obstruc-
ns in V. lienalis. The etiology included severe
troenteritis, pyle-thrombosis, ligation of portal
n, Boeck's sarcoid, and pancreatitis. Three
ients received no operations. The operations in
the remaining 4 included: portacaval shunt end-to-side; splenectomy and spleno-renal shunt end-to side either singly or with a mesocaval shunt; and a spleno-renal shunt side-to-side plus a portacaval shunt end-to-side. Three of the operations resulted in no complications; postoperative thrombosis and rebleeding occurred after 3 operations. One of the 7 patients is died; the others are alive and well. It is thought that surgery might not have been necessary for all 4 patients. None of them bled heavily, and it is known that patients with extrahepatic obstruction tolerate the bleeding episodes better than do patients with cirrhosis of the liver. It is concluded that the only way to distinguish the patients who need surgical interventions from those with spontaneous regression is by repeated splenoportographic studies.

2371 'ERYTHROPOIETIC' PROTOPORPHYRIA AND CIRRHOSIS IN SISTERS. *(E.)* Thompson,

R. P. H.; Molland, E. A.; Nicholson, D. C.; Gray, C. H. (St. Thomas' Hosp., London, England). *Gut* 14(12):934-938, 1973.

The clinical and histopathological features of 2 sisters with erythropoietic protoporphyria and liver disease are described. There was no history of photosensitivity in their other 9 siblings or in the parents. These sisters had life-long photosensitivity, followed later by severe blistering. They both became jaundiced and died at the age of 31 with cirrhosis. The retrospective diagnoses of erythropoietic protoporphyria were made from the photosensitivity from childhood, greatly raised levels of fecal and proto- and coproporphyrins, and from the raised levels of protoporphyrin in the plasma of 1 sister and of protoporphyrin and coproporphyrin, in red cells of the second sister. Both the sisters thought that jaundice followed exposure to sun, but a careful history revealed that the intense blistering occurred only after exposure when jaundice had developed. Serum bilirubin, however, correlated poorly with the severity of photosensitivity and with the excretion of porphyrins. A microscopical postmortem examination of the livers showed cirrhosis with bile duct proliferation and a lymphocyte infiltration of the septa. Dark-brown pigment was present and distributed in granules within liver cells, in Kupffer cells, as plugs in canaliculi and in the septa. The characteristic red autofluorescence under ultraviolet light, and birefringent crystals and Maltese cross figures under polarized light were demonstrated. There was widespread cholestasis.

2372 AUSTRALIA ANTIGEN AND PRIMARY BILIARY CIRRHOSIS. *(E.)* MacSween, R. N. M.;

Laiwah, A. A. C. Y.; Busuttil, A. A.; Thomas, M. A.; Ross, S. K.; Watkinson, G.; Millman, I.; Blumberg, B. S. (Dept. Pathol., Univ. Glasgow, Scotland). *J. Clin. Pathol.* 26(5):335-339, 1973.

Sera from 64 patients with primary biliary cirrhosis were examined for Australia antigen. Lymphocyte transformation studies were performed on peripheral blood lymphocytes in 24 patients with primary biliary cirrhosis and 24 age- and sex-matched controls, using as transforming agent a serum rich in Australia antigen and which had been shown to produce lymphocyte transformation in patients who had recovered from a previous clinical attack of Australia antigen-positive serum hepatitis. On immunodiffusion and immunoelectrophoresis testing, detectable quantities of Australia antigen were present in 10 of 64 sera (16%), an incidence significantly different from the 3% in controls. In only 1 of 24 patients with primary biliary cirrhosis did the peripheral blood lymphocytes transform in response to an Australia antigen-rich serum, the lymphocytes showing a 3.5-fold increase in ^{14}C-thymidine incorporation as compared with unstimulated controls. No lymphocyte transformation was obtained in lymphocytes from the 24 control patients. It is suggested that the finding of a statistically increased frequency of Australia antigen in the patients with primary biliary cirrhosis is of biological significance. The failure to show delayed hypersensitivity to Australia antigen in these patients could be a manifestation of the reported impairment of cellular immunity in this disease, and could offer an explanation for the apparent persistence of the virus in some instances.

2373 TOXIC METABOLITES IN THE BRAINS OF PATIENTS WITH CIRRHOSIS AND PORTACAVAL SHUNT.

(Ger.) Lesch, P. (Med. Coll., Hannover, Germany). *Dtsch. Med. Wochenschr.* 98(41):1929-1931, 1973.

The toxic metabolites, p-hydroxyphenylacetic and p-hydroxyphenyllactic acids, were isolated from the brain of a patient who died in hepatic coma 12 yr after undergoing surgery for creation of a portacaval shunt. The hepatic coma resulted from posthepatitic cirrhosis and secondary liver injury induced by alcohol. The content of p-hydroxyphenylacetic acid was 74.9 nM/100 g wet weight and that of p-hydroxyphenyllactic acid was 25.8 nM/100 g wet weight of tissue. Some of the p-hydroxyphenylacetic acid may have formed by decarboxylation of p-hydroxyphenylpyruvic acid during gas chromatography. Qualitative analysis revealed that p-hydroxyphenylacetic acid was also present in the brain of another patient wit the same history, but these toxic metabolites were not detected in the brains of "normal" patients or patients who died of hepatic coma but did not have portacaval shunts. It is suggested that interaction may occur between lipids in the brain and these p-hydroxycarboxylic acids which could cause allosteric enzyme inhibition and produce metabolic disturbances which would result in changes in lipid structure. This would have a deleterious effect on the selectiv permeability of interfaces which, in conjunction with other metabolic abnormalities (e.g. dehydration increased blood levels of amino acids, low blood sug levels, etc.), might result in decompensation of cerebral metabolism which is clinically manifested as hepatic coma.

2374 DECREASED ARTERIAL OXYGEN CONCENTRATIONS AND HEMODYNAMIC CHANGES IN CIRRHOSIS.

(Ger.) Baltzer, G.; Arndt, H.; Martini, G. A. (Med. Clin., Univ. Marburg/Lahn, Germany). *Klin. Wochenschr.* 51(21):1033-1042, 1973.

2375 INCREASE IN HEPATIC SIZE AFTER SPLENECTOMY FOR PORTAL VEIN THROMBOSIS.

(E.) Spencer, R. P.; Antar, M. A.; Touloukian, R. J. (Yale Univ. Sch. Med., New Haven, Conn.). *J. Nucl. Med.* 14(11):854-855, 1973.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

2376 ENZYME HISTOCHEMISTRY OF THE LIVER IN EXTRAHEPATIC BILIARY OBSTRUCTION. A COMPARISON BETWEEN MAN, DOG, AND RAT.

(E.) Hagerstrand, I. (Inst. Pathol., Univ. Lund, Malmo, Sweden). *Acta Pathol. Microbiol. Scand.* [*A*] 81(6):737-750, 1973.

Morphological and enzyme histochemical changes during extrahepatic biliary obstruction in the liver tissue of man, dog and rat were compared. The differences in morphological changes were mainly quantitative. Ductular proliferation was less marked and occurred later in livers of man and dog than in rat liver and there were more cellular changes centrolobularly in the livers of the former 2 species. The qualitative differences consisted of lack of cholestasis in the rat liver and of focal necroses in the dog liver. Staining for succinic dehydrogenase and glucose-6-phosphatase showed decreased activity while lactic dehydrogenase and mono-amine oxidase remained unchanged. The lysosomal enzyme activities (acid phos phatase and beta-glucuronidase) were increased in hepatocytes and Kupffer cells, but the increase was most evident in connection with biliary pigment in livers of dog and man. The membrane-associated hydr lases (adenosine triphosphatase, alkaline phosphatas leucine aminopeptidase, gamma-glutamyl transpeptidas varied in the 3 species with alternating increase an decrease at the sinusoids and canaliculi. The incre amount of reaction product in hepatocytes and the in creased numbers of positive Kupffer cells revealed b staining for acid phosphatase and beta-glucuronidase activity are correlated with the ultrastructural fin ing of increased numbers of lysosomes and phagosomes both in hepatocytes and in Kupffer cells. Thus, the is reason to interpret the increased staining as an increase in numbers of enzyme molecules. The serum values for gamma-glutamyl transpeptidase activity in

ıe 3 species varied with the histochemical patterns.
ıe serum increase was by far the highest in man.
ıe smallest rise was observed in the rat. In this
ıimal, the proliferating ductular epithelium showed
ctivity. In the dog liver there was activity of
amma-glutamyl transpeptidase in periportal canaliculi
ıd a moderate increase was noticed in serum activity.

377 METABOLISM OF LITHOCHOLIC ACID-24-^{14}C IN EXTRAHEPATIC BILIARY ATRESIA. *(E.)*

rman, A.; Strandvik, B. (Karolinska Inst.,
ockholm, Sweden). *Acta Paediatr. Scand.* 63(1):
-96, 1974.

ithocholic acid-24-^{14}C was given to 2 infants with
trahepatic biliary atresia. After oral admini-
ration about half of the isotope was absorbed.
ter parenteral administration, about half of the
sotope was excreted in the urine for 3 days.
ithocholic acid was transformed to a small extent
more polar compounds. These metabolites were
t cholic, chenodeoxycholic, α- or β-muricholic,
ocholic, hyodeoxycholic or ursodeoxycholic acids.
st of the lithocholic acid was excreted as sul-
ate esters of tauro- and glycolithocholic acid.
sulphate ester of lithocholic or free lithocholic
id was excreted. The high degree of sulphation
lithocholic acid conjugates observed in this
vestigation and the low quantitative excretion of
ithocholic acid previously observed suggest that
ithocholic acid is no important factor in the
pid progression of cirrhosis observed in extra-
patic biliary atresia.

78 BILIARY LIPID OUTPUTS IN YOUNG WOMEN WITH CHOLESTEROL GALLSTONES. *(E.)*

Grundy, S.
; Duane, W. C.; Adler, R. D.; Aron, J. M.; Metzger,
L. (Phoenix Indian Med. Ctr., Ariz.). *Metabolism*
(1):67-73, 1974.

patic secretions of biliary lipids were determined
8 young women with cholesterol gallstones and 14
ite women without gallstones. All of the gallstone
tients were non-Indian; 7 were white and 1 was
ack. Hourly outputs of biliary cholesterol were
gnificantly greater in gallstone patients than in
ite controls. This increased cholesterol output was
major factor in the production of lithogenic bile.
e greater cholesterol output in gallstone patients
s apparently related to obesity. Despite an in-
eased hepatic secretion of cholesterol, secretion
tes of bile acids were relatively low in gallstone
tients. However, there was considerable overlap
tween secretion rates of bile acids in subjects
th and without stones, and it was not demonstrated
at an absolute deficiency of bile acids existed
gallstone patients. Nevertheless, the contribution
an increased output of biliary cholesterol to the
rmation of lithogenic bile was clearly evident in
r patients. This study illustrates a mechanism for
thogenic bile formation, excessive secretion of
olesterol without a compensatory increase in bile-
id outputs. It is suggested that this mechanism
y be important for gallstone formation in obese
ung women regardless of their racial backgrounds. One approach to reduction of bile lithogenicity would be to expand the enterohepatic circulation of bile acids, especially when a deficiency exists. This might be accomplished either by enhancing bile-acid synthesis or through oral administration of bile acids. Another technique could be to decrease biliary outputs of cholesterol. In obese patients, weight reduction causes a lowering of cholesterol synthesis, and it thus seems likely that weight reduction would also decrease hepatic secretion of cholesterol. Another means for reducing biliary cholesterol may be oral administration of chenodeoxycholic acid. This latter approach seems particularly promising in view of the potential usefulness of this bile acid for gallstone dissolution.

2379 ADENOCARCINOMA OF THE AMPULLA OF VATER ASSOCIATED WITH FAMILIAL POLYPOSIS COLI: REPORT OF A CASE. *(E.)*

Mir Madjlessi, S. H.; Farmer, R. G.; Hawk, W. A.; Turnbull, Jr., R. B. (Cleveland Clin. Fdn., Ohio). *Dis. Colon Rectum* 16(6):542-546, 1973.

A 40 yr old male was treated with prednisone (20 mg/day) for jaundice from suspected viral hepatitis. Further studies proved viral hepatitis was not the cause of the jaundice, but rather the patient was suffering from diffuse polyposis coli and adenocarcinoma of ampulla of Vater. Laboratory data reported total bilirubin, 11.1 mg/100 ml; SGOT, 140 U/100 ml; and alkaline phosphatase, 160 Ka units/100 ml. Familial history included the deaths of his mother and 1 sister due to cancer of the colon, 1 brother had diffuse polyopsis of the colon, 1 of 2 daughters and his 1 son had had subtotal colectomies for diffuse polyposis coli. Both of these siblings had sebaceous cysts of the scalp. It is suggested that coexistent ampullary carcinoma should be considered in all patients with familial polyposis coli, Gardner's syndrome, or their variants. The ampullary area should be carefully examined with conventional roentgenographic methods. An aggressive approach to remove the ampullary carcinoma seems favored in that the outcome of patients so treated is generally good. It is further suggested that the combination of familial polyposis coli or Gardner's syndrome and ampullary carcinoma may represent a new nosologic entity.

2380 EXPERIENCES IN THE MANAGEMENT OF SURGICALLY CORRECTABLE BILIARY ATRESIA. *(E.)*

Arima, E.; Fonkalsrude, E. W.; Neerhout, R. C. (Univ. Calif. Sch. of Med., Los Angeles). *Surgery* 75(2):228-232, 1974.

The experiences at the UCLA Hospital with 10 patients who have undergone biliary-enteric anastomosis for extrahepatic biliary atresia during the past 16 yr is summarized. There were 7 females and 3 males. Their ages at time of operation ranged from 6 weeks to 4 1/2 yr. The types of operations included: Choledochoduodenostomy, revision of choledochojejunostomy, tube drainage of duct, splenectomy for hypersplenism, mesocaval shunt for varices, hepaticoduodenostomy, longmire procedure, persistent jaundice, revision of longmire procedure, closure of enteric fistula, open-liver biopsy, and catheter drainage of duct. The complications included: cholangitis, biliary obstruction, mild cirrhosis, sepsis, hepatomegaly, varices, intestinal obstruction, enteric fistula, hepatic failure, ascites, persistent jaundice, and mild and transient ascites. Five of the patients died. Three patients had 3 different operations, 1 had 4, 3 had 2 operations, and 3 had 1 operation. It is concluded that the evidence from this study supports the view that when drainage is established before the age of 4 months in a patient with a correctable form of biliary atresia, long-term survival is possible. When drainage is deferred an additional few months, biliary cirrhosis becomes irreversible, minimal quantities of bile may be drained, and early death usually results.

2381 EMPYEMA OF THE GALLBLADDER DUE TO HAEMOPHILUS PARAHAEMOLYTICUS WITH A BRIEF REVIEW OF ITS ROLE AS A PATHOGEN.

(E.) Parsons, M.; Faris, I. (Middlesex Hosp. Med. Sch., London, England). *J. Clin. Pathol.* 26:604-605, 1973.

A case history of a 40-year-old policeman with empyema of the gallbladder caused by *Haemophilus parahemolyticus* is reported. At operation, the gallbladder was embedded in the liver. While being freed it was inadvertently ruptured and thick pus escaped. This was immediately aspirated into a syringe and sent for culture. There were stones in the gallbladder but none in the common duct. Gram staining of the pus showed many small pleomorphic Gram-negative rods. After 18 hr incubation on Columbia agar with 5% horse blood, it produced a pure growth of small grey β-hemolytic colonies which were facultatively anerobic. On nutrient agar there was abundant growth round discs containing V and X + V factors but none around that contained X factor only. This was repeated on subculture from around the V factor disc. The organism was nonmotile, indole negative, and reduced nitrates. Histology of the gallbladder showed marked inflammatory thickening of the wall, with gross muscle hypertrophy and intramural diverticula. The stones were of cholesterol. How the organism reached this patient's gallbladder is not certain. There may have been a transient bacteremia, as is known with other upper respiratory tract commensals, in which the bacteria came through the gallbladder wall. This would be in accord with the current theory that bacteria in the bile tend to get there from the bloodstream through the wall rather than by ascending from the gut.

2382 URINARY BILE ACID CONJUGATES IN EXTRAHEPATIC BILIARY ATRESIA.

(E.) Norman, A.; Strandvik, B.; Ojamae, O. (Dept. Clin. Chem., Univ. Linkoping, Sweden). *Acta Paediatr. Scand.* 63(1): 97-102, 1974.

The urinary excretion of bile acid conjugates was studied after the administration of 24-^{14}C-labelled chenodeoxycholic acid and cholic acid and their corresponding glycine conjugates labelled with glycine-1-^{14}C in 5 infants with extrahepatic biliary atresia. Chenodeoxycholic acid-24-^{14}C and chenodeoxycholyl[1-^{14}C]glycine were mainly excreted in the form of labelled metabolites with the thin layer chromatography behavior of monosulphates of tauro- and glycochenodeoxycholate and glycochenodeoxycholate, respectively. Most of the cholic acid-24-^{14}C and the choly[1-^{14}C]glycine were found to be excreted in the form of glycocholate. All labelled bile acids were excreted in conjugated form.

2383 ALTERATION OF BILE SALT METABOLISM BY DIETARY FIBRE (BRAN).

(E.) Pomare, E. W.; Heaton, K. W. (Bristol Roy. Infirm., England). *Br. Med. J.* (5887):262-264, 1973.

Feeding dietary fiber in the form of bran induced changes in bile salt metabolism in 5 people with intact gall bladders. There was evidence of reduced dehydroxylation of bile salts; the proportion of deoxycholate conjugates in bile was reduced and the transfer of radioactivity from labelled taurocholate to deoxycholate was decreased. These findings, which were independent of changes in intestinal transit rate, imply that bran reduced the degradation bile of salts by colonic bacteria. This property of bran accords with recent theories that fiber-depleted diets favor the degradation of bile salts in the colon. These findings may be relevant to the etiology of large bowel cancer.

2384 TWENTY-FIVE-YEAR SURVIVAL AFTER SURGERY FOR COMPLETE EXTRAHEPATIC BILIARY ATRESIA. A CASE REPORT.

(E.) Berenson, M. M.; Garde, A. R.; Moody, F. G. (VA Hosp., Salt Lake City, Utah). *Gastroenterology* 66(2):260-263, 1974.

A case history is presented of a patient who at the age of 12 weeks underwent cholangioduodenostomy for treatment of complete atresia of the common bile duct. After surgery, her course was punctuated by episodes of cholangitis and jaundice. When she was 25 years of age, a liver biopsy showed biliary cirrhosis. Percutaneous cholangiography revealed dilated and deformed intrahepatic biliary ducts containing stones. Surgical removal of the stones and revision of the cholangioduodenal anastomosis was performed. Intrahepatic cholelithiasis has not previously been reported as a complication of this disorder. Her survival is the longest reported in the world literature for this condition, and emphasizes the need to vigorously pursue potentially operable cases.

2385 EARLY AND DELAYED OPERATION IN ACUTE GALLSTONE DISEASE.

(E.) Sokhi, G. S.; Longland, C. J. (Roy. Infirm., Glasgow, Scotland). *Br. J. Surg.* 60(12):937-939, 1973.

A comparison is presented of patients who had gallbladder operations during the emergency admission and those who had later operations. There were 60 patients who had delayed operations and received orthodox conservative management of the acute attack and discharge from the hospital, followed by read-ission at a later date and definitive surgery. The ean age of this group was 58 yr and the range was 1 to 81. A group of 52 patients received an early peration, during the first admission. The mean age as 56 yr and the range was 17 to 80. There were 45 atients who received no operation. The patients n this mixed group either died without operation 3) or after cholecystostomy alone (1), declined peration (5), or failed to return after initial onservative treatment and discharge from the hospital 11). A further 25 patients were considered unfit or definitive operation. The mean age was 63 yr, he range was 23 to 87. After delayed operation, here was 1 death. After early operation there were deaths. The highest mortality was in the patients ho had no definitive operation, 4 deaths. The roportion of patients having recorded complications as about the same following delayed and early peration. Wound infection and pulmonary infection ccurred most often. Cardiac and renal problems ere the next most frequent complications. The ean total hospital stay for the delayed operation atients, including the emergency and elective ad- issions and any intermediate admissions, was 30 days. or those patients in whom surgery was completed at he first admission, the mean total hospital stay as 25 days. It is concluded that among the patients urveyed with acute gallstone disease, there was no tatistically significant difference in the operative ortality between the patients who were operated on uring the emergency admission and those having elayed operation at a second admission. The fre- uency of recorded postoperative complications were early the same in both groups.

386 INHIBITION OF BILIRUBIN EXCRETION IN MAN DURING DEHYDROCHOLATE CHOLERESIS. *(E.)*

loomer, J. R.; Bover, J. L.; Klatskin, G. (Yale niv. Sch. Med., New Haven, Conn.). *Gastroentero- ogy* 65(6):929-934, 1973.

odium dehydrocholate (Decholin), was given intra- enously to 5 fasting patients with external bili- ry drainage to determine its effect on bilirubin xcretion. The range of bile flow for these patients uring control periods was 0.31 to 0.44 ml/min, and or bile bilirubin concentrations was 25.9 to 57.6 mg/ 00 ml. Bile bilirubin concentrations decreased to evels that were 8 to 18% of control values during he 60- to 70-min period after Decholin administra- ion. In each patient the decrease in bile bili- ubin concentration was greater than could be ac- ounted for by the dilutional effect of increased ile water formation, and the rate of bilirubin xcretion in bile diminished after Decholin admini- tration. Studies with intravenously administered ilirubin-^{3}H in 2 patients demonstrated that the umulative recovery of label in bile was slower fter giving Decholin, and the plasma disappearance ate of unconjugated bilirubin-^{3}H was delayed. The ata indicate that Decholin inhibits bilirubin ex- retion in man despite its choleretic effect.

387 BILE SALT METABOLISM IN PATIENTS WITH GALLSTONES IN FUNCTIONING GALLBLADDERS. *(E.)*

Pomare, E. W.; Heaton, K. W. (Roy. Infirm., Bristol, England). *Gut* 14(11):885-890, 1973.

Isotopic bile salt studies were performed in 8 middle-aged women with radiolucent gallstones in functioning gallbladders and in 10 matched controls. In the gallstone patients the size of the bile salt pool was reduced by 37% to 1.79 g, but there was considerable overlap with the normal subjects. The cholate and chenodeoxycholate pools were reduced, but the deoxycholate pool was normal in size. There were changes in bile salt metabolism which resembled those found after cholecystectomy but were less marked. This suggests that in gallstone disease the storage capacity of the gallbladder is impaired. This may contribute to the small bile salt pool, but it is unlikely to be the sole or even the major cause.

2388 THE COMPLETION CHOLANGIOGRAM: FAILURE TO EMPTY DUE TO PSEUDO-OBSTRUCTION. *(E.)*

Watkins, G. L. (Washington Univ. Sch. Med., St. Louis, Mo.). *Surgery* 74(5):650-653, 1973.

A total of 508 primary and 19 secondary biliary tract operations were reviewed. Of the 177 common duct explorations, stones were found in 85 (48%). Of the 162 completion cholangiograms performed, 14 failed to empty. Of these 14, 12 were cases where stones were found in the common duct, suggesting that the added trauma to the duct system occurring when one finds and removes stones has something to do with the degree of edema or spasm that follows. No reflux was seen in the pancreatic ducts at the time of the completion cholangiograms, in spite of the sometimes considerable intraductal pressure induced by the injection. However, in the majority of cases, pancreatic reflux was seen on postoperative cholangiograms. It is thus suggested that obstruction is not at the ampulla but in the intramural segment of the common duct, probably at the level of the pars superior of the choledochal sphincter, produced by spasm of this sphincter as well as the wall of the duodenum with local edema also causing a significant effect.

2389 INCREASED FORMATION OF URSODEOXYCHOLIC ACID IN PATIENTS TREATED WITH CHENODEOXYCHOLIC ACID. *(E.)*

Salen, G.; Tint, G. S.; Eliav, B.; Beering, N.; Mosbach, E. H. (Manhattan VA Hosp., N.Y.). *J. Clin. Invest.* 53(2):612-621, 1974.

The formation of ursodeoxycholic acid, the 7β-hydroxy epimer of chenodeoxycholic acid, was investigated in 3 subjects with cerebrotendinous xanthomatosis and in 4 with gallstones. Total biliary bile acid composition was analyzed by gas-liquid chromatography before and after 4 months of treatment with chenodeoxycholic acid (0.75 g/day). Individual bile acids were identified by mass spectrometry. Before treatment, bile from cerebrotendinous xanthomatosis subjects contained cholic acid, 85%; chenodeoxycholic acid, 7%; deoxycholic acid, 3%; allocholic acid, 3%; and unidentified steroids, 2%; while bile from gallstone subjects contained cholic acid, 45%; chenodeoxycholic acid, 43%; deoxycholic acid, 11%, and lithocholic acid, 1%. In all subjects, 4 months of chenodeoxycholic acid therapy increased the proportion of this bile acid to approximately 80% and decreased cholic acid to 3% of the total biliary bile acids; the remaining 17% of bile acids were identified as ursodeoxycholic acid. After the i.v. injection of [^{3}H]chenodeoxycholic acid, the specific activity of biliary ursodeoxycholic acid exceeded the specific activity of chenodeoxycholic acid, and the resulting specific activity decay curves suggested precursor-product relation. When [^{3}H]7-ketolithocholic acid was administrated to another patient treated with chenodeoxycholic acid, radioactivity was detected in both the ursodeoxycholic acid and chenodeoxycholic acid fractions. These results indicate that substantial amounts of ursodeoxycholic acid are formed in patients treated with chenodeoxycholic acid, presumably from chenodeoxycholic acid via 7-ketolithocholic acid. These results indicate that substantial amounts of ursodeoxycholic acid are formed in patients treated with chenodeoxycholic acid, presumably from chenodeoxycholic acid via 7-ketolithocholic acid.

2390 CONFIRMATION OF POSTCHOLECYSTECTOMY BILIARY DYSKINESIA BY ELEVATION OF SERUM TRANSAMINASES (GOT AND GPT) AFTER INJECTION OF MORPHINE?

(E.) Holtzer, J. D.; Hulst, S. G. T. (Univ. Hosp., Utrecht, Netherlands). *Acta Med. Scand.* 194(3):221-224, 1973.

The effect of i.m. injection of morphine on the serum concentrations of bilirubin, alkaline phosphatase, GOT, GPT, LDH and amylase has been studied in 39 cholecystomized patients and 62 patients without previous cholecystectomy. Most of the cholecystectomized patients in whom the injection of morphine provoked a reaction of abdominal pain showed increased serum activity of both GOT and GPT 8 hr after the injection of morphine. The results suggest that this morphine-enzyme-pain provocation may be helpful in differentiating dyskinesia of the sphincter Oddi from other postcholecystectomy abdominal complaints.

2391 PHARMACOLOGY OF GENTAMICIN IN THE BILIARY TRACT OF HUMANS.

(E.) Mendelson, J.; Portnoy, J.; Sigman, H. (Jewish Gen. Hosp. Montreal, Canada). *Antimicrob. Agents Chemother* 4(5):538-541, 1973.

Serum and biliary tract levels of gentamicin were determined in 62 patients. Group 1 included 41 who were about to undergo cholecystectomy; group 2 was comprised of 21 who had had cholecystectomies with common bile duct exploration followed by insertion of a T-tube. There were 20 males and 42 females, with ages ranging from 17 to 80 yr. In Group 1, bile was aspirated from the gallbladder at operation at a recorded interval after an i.m. injection of gentamicin. In Group 2, T-tube bile was obtained from the drainage bag which was emptied completely between sampling. The interval in Group 1 between the injection of gentamicin and the sampling of bile and serum ranged from 20 to 120 min. The dose of gentamicin varied from 80 to 120 mg i.m. In only 3 patients studied were serum gentamicin levels greater than 5 μg/ml. The gallbladder gentamicin levels were less than 1 μg/ml in 32 of the 41 patients. Similar ranges in serum gentamicin levels were obtained when 80, 100, or 120 mg of gentamicin was used. No relationship was noted between the gentamicin levels in serum or bile and the time interval between the injection and sampling. In 16 of 21 patients of Group 2 with common duct T-tubes studied, a single dose of gentamicin was given and ranged from 100 to 120 mg i.m. Five additional patients received 120 mg every 8 hr for 4 doses. In the 21 patients studied, only 8 had serum gentamicin levels of 5 μg/ml or greater. No cumulative effect was seen in serum or bile levels when gentamicin was administered every 8 hr for 4 doses. The clinical significance of these data is uncertain, since the importance of high gallbladder bile levels of antibiotic in the medical management of cholecystitis has not been determined.

2392 INTRAHEPATIC ARTERY ANEURYSM ASSOCIATED WITH HEMOBILIA. A CASE REPORT.

(E.) Berenson, M. M.; Freston, J. W. (Univ. Coll. Med., Utah, Salt Lake City). *Gastroenterology* 66(2):254-259, 1974.

The case of a 51-year-old housewife with intermittent upper gastrointestinal hemorrhage beginning 1 month after cholecystectomy is presented. At laparotomy the common bile duct was found to be greatly dilated. Operative cholangiography revealed dilation of the biliary radicles and many radiolucent spots. The bile duct was opened revealing many blood clots. No tumor was found in the pancreas. Four needle biopsies of the liver were obtained which revealed bile stasis and edema in the portal tracts, but no evidence of cholangitis or parenchymal liver disease. Active bleeding was not present, and it was elected to perform a choledochoduodenostomy and ligation of the common hepatic artery proximal to the gastroduodenal artery. The postoperative course was uncomplicated. The patient's liver studies improved, and T-tube cholangiography revealed diminution in the size of the common bile duct. A celiac angiogram obtained postoperatively revealed excellent collateral blood flow via splenic and pancreaticoduodenal arteries which supplied the liver by way of reverse flow through the gastroduodenal artery. Management of intrahepatic aneurysms depends on the nature and the extent of the lesion. Segmental hepatic resection definitively removes the source of bleeding but may be attended by an increased surgical morbidity. Ligation of the hepatic artery proximal to the gastroduodenal artery in this patient has apparently prevented recurrent episodes of hemobilia and restored her hepatobiliary system towards normalcy.

GENERAL

405 DETECTION OF A NEW VIRUS BY ELECTRON MICROSCOPY OF FAECAL EXTRACTS FROM CHILDREN ITH ACUTE GASTROENTERITIS. *(E.)* Bishop, R. F.; avidson, G. P.; Holmes, I. H.; Ruck, B. J. (Roy. hildren's Hosp., Melbourne, Australia). *Lancet* 7849):149-151, 1974.

lectron microscopy of negatively stained fecal exracts revealed particles resembling orbiviruses in 1 of 14 children with acute non-bacterial gastroeneritis. No such particles were observed in fecal xtracts from 9 control children. The method of ifferential centrifugation for extraction of feces s simple, quick, and more sensitive than duodenal iopsy for detecting the virus. Combining results rom duodenal mucosa and feces, orbivirus particles ere observed by electron microscopy in 81% of childen with sporadic gastroenteritis in Melbourne. his high frequency shows that this orbivirus is he most important etiological agent in sporadic astroenteritis in children in Melbourne. In morhology and biological characteristics it resembles ery closely the viruses of epizootic diarrhea of nfant mice and calf scours. The need for duodenal iopsy to identify this virus is now eliminated. iming of fecal collection in relation to onset of llness is important. Fecal specimens from 1 child ere positive on day 2 but negative on day 4 of the illness. This technique of fecal extraction will facilitate the epidemiological investigation of the worldwide distribution of this virus.

2406 YERSINIOSIS IN CHILDREN. *(E.)* Delorme, J.; Laverdiere, M.; Martineau, B.; Laflour, L. (Sainte-Justine Hosp. Montreal, Canada). *Can. Med. Assoc. J.* 110(3):281-284, 1974.

Sixty-five strains of *Yersinia enterocolitica* were isolated from stool specimens obtained from 35 patients over a 12-month period. Cultures were made either from a rectal swab or a stool specimen. Of 82 stool cultures from 35 patients, 65 were positive for *Y. enterocolitica.* At least 12 patients had both negative and positive cultures. *Y. enterocolitica* was isolated together with a salmonella species in 2 patients. Strains of *Y. entercolitica* appeared as short gram-negative rods which within 24 hr on SS agar produced tiny lactose-negative, translucent, homogeneous colonies with a hazy rim. The male/female ratio was 1.3:1. Almost 33% of the patients were under 1 yr of age. There was a clearly higher incidence during the months of March, July, and November. The clinical manifestations in *Y. enterocolitica* infections include: acute diarrhea (22 cases), chronic diarrhea (4 cases), nausea and vomiting (12 cases), abdominal pain (6 cases), temperature greater than 101 F (6 cases), and skin rash (2 cases). All patients received only general supportive measures directed to the clinical pattern later found to be caused by *Y. enterocolitica*. Such treatment was followed by a notable improvement within 2 days and in 31 patients complete clinical remission was achieved. In 1 patient, specific treatment with tetracycline was given because of chronicity of the illness and weight retardation. In 2 patients, chloramphenicol was given because the response to the supportive treatment was slow. Yersinia infection in humans involves chiefly the digestive system. Two forms have been described, gastroenteritis and mesenteric lymphadenitis. It is concluded that further North American studies are required to clarify the pathogenicity and epidemiology of this organism.

2407 GASTROINTESTINAL MANIFESTATIONS OF ADVERSE DRUG REACTIONS. *(E.)* Stewart, R. B.; Cluff, L. E. (Coll. Pharm., Univ. Florida, Gainesville). *Am. J. Dig. Dis.* 19(1):1-7, 1974.

Analysis was made of digestive reactions to drugs occurring in hospitalized and nonhospitalized patients. A total of 3164 inpatients were studied, 1583 male and 1581 female, average age 49 yr. The average number of drugs administered per patient was 9.5. Adverse drug reactions of all types were detected in 505 patients (15.9%). Digestive system reactions were detected in 136 (4.3%). White women had a higher incidence of gastrointestinal reactions than did black women, white men or black men. The most common drugs associated with gastrointestinal reactions were potassium chloride syrup, heparin, dioctyl sodium sulfosuccinate, aluminum and magnesium hydroxide suspension, ampicillin, and guanethidine. Potassium chloride syrup was frequently responsible for nausea and vomiting. Aluminum and magnesium hydroxide suspension caused intestinal reactions. heparin caused intestinal bleeding. Women experienced a significantly greater rate of gastrointestinal reactions to levodopa and guanethidine than men. Aspirin was the leading etiological agent responsible for gastrointestinal reactions, followed by digoxin and indomethacin. In a study of 612 outpatients (233 men and 379 women), 83 reactions to drugs affecting the gastrointestinal system were reported with women having a significantly greater share than men. Classes of drugs affecting the gastrointestinal system were nonnarcotic analgesics, narcotic analgesics, and antiinfective drugs, totalling 77.1% of all reactions. It is suggested that the difference in frequency of nausea, vomiting, and diarrhea in men and women may indicate a predisposition of women to these manifestations due to differences in gastrointestinal physiology. It is also suggested that the anxiety and fear inherent in hospitalization itself may produce the more frequent occurrence of abnormal digestive reactions to drugs in hospitalized versus nonhospitalized patients.

2408 INGESTION OF MINERAL ACID. *(E.)* Jelenko, III, C.; Story, J.; Ellison, Jr., R. G. (Med. Coll. Georgia, Augusta). *Am. Surg.* 40(2):97-104, 1974.

Five case histories are presented which discuss the accidental or intentional ingestion of concentrated sulfuric, hydrochloric, or muriatic (commercial grade HCl) acid. The first subjec intentionally ingested muriatic acid. A gastrojejunostomy was performed. The second patient intentionally took hydrochloric acid. An end-to-end gastroileostomy was performed, a tube duodenostomy was placed, a T-tube was inserted in the common duct, and a tracheotomy was performed. He died on his eleventh postoperative day. The third patient accidentally placed approximately one glassful of sulfuric acid in his mouth. He did not swallow, but immediately spat the acid out. He hurriedly washed his mouth with large quantities of water. The severe burns of the entire mucous membrane of the mouth resolved over a 6-day period. The fourth patient mistakenly drank 50% sulfuric acid thinking it was water. He underwent gastrostomy and esophageal dilatation. Retrodilatation of the esophagus was performed subsequently on several occasions, but over a period of 6 days following his gastrostomy he had several episodes of upper gastrointestinal bleeding. The fifth patient accidentally drank a good swallow of 50% sulfuric acid. Exploration revealed the stomach and small bowel down to the ileum to be edematous, dilated and filled with fluid and air. The distal 4 cm of the stomach and proximal 4 cm of the duodenum were resected. The proximal duodenum was closed around a No. 22 French mushroom catheter, the distal stomach was closed, the necrotic areas on the stomach were inverted using interrupted Lembert sutures, and a posterior gastrojejunostomy was performed in the Polya manner. A T-tube was placed in the common duct. Three large Penrose drains were placed in the area of the liver, the area of the anastomosis and in the right gutter. Two Penrose drains were placed, one at the area of the gastroesophageal junction and the other anterior to the gastrojejunostomy. A sump drain was placed in the area of the first part of the duodenum. The following conditions were observed in these 5 patients: strictures of the esophagus, gastroesophageal junction and gastric antrum; coagulation necrosis of the stomach, duodenum, jejunum, and ileum; pancreatitis; omental fat necrosis, and severe peritonitis.

2409 RELATIONSHIP BETWEEN HEPATIC MORPHOLOGY AND CLINICAL AND BIOCHEMICAL FINDINGS IN MORBIDLY OBESE PATIENTS. *(E.)* Manes, J. L.; Taylor, H. B.; Starkloff, G. B. (St. Louis Univ. Med. Ctr., Mo.). *J. Clin. Pathol.* 26(10):776-783, 1973.

The interrelations between clinico-biochemical parameters and hepatic morphology was studied in 166 female and 52 male markedly obese patients. There was a statistically significant association of carbohydrate metabolism disturbance with increasing age and corpulence and, in women, with hyperuricaemia and morphological alterations of the liver. Menstrual irregularities also correlated well with hepatic morphology. The livers frequently exhibited steatosis, but other morphological changes were mild. Compared with women, men had higher triglyceride values, more severe hepatic involvement, and poorer correlation of carbohydrate disturbances with hepatic histology. The results indicate a central role of the impaired carbohydrate utilization in the biochemical and epatic alterations of obesity.

2410 INCREASED JEJUNAL IgA SYNTHESIS IN VITRO DURING ACUTE INFECTIOUS NONBACTERIAL GAS-ROENTERITIS. *(E.)* Agus, S. G.; Falchuk, Z. M.; Sessoms, C. S.; Wyatt, R. G.; Dolin, R. (Natl. Inst. llergy Infect. Dis., Bethesda, Md.). *Am. J. Dig. Dis.* 19(2):127-131, 1974.

Employing a solid-phase immunoadsorbant technique, *n vitro* jejunal IgA production was measured in olunteers before, during, and after infection with he Norwalk agent of acute infectious nonbacterial astroenteritis. In 4 volunteers who became ill with his disease, there was a significant rise in jejunal gA production in convalescent biopsies taken 2 weeks ollowing infection, when compared with changes in he 3 volunteers who did not become ill. The possible ole of local immunity in the response to nonbacter-al gastroenteritis is discussed. Although it is ossible that the early rise in IgA production seen n volunteers may represent an anamnestic response o the Norwalk agent, 2 of these volunteers who howed early rises also developed clinical illness. he clarification of this concept will depend on the evelopment of serologic techniques with which mmunity to agents such as Norwalk can be studied.

GENERAL

Parasitology

2521 PSEUDOLYMPHOMAS OF THE COLON: TWO CASES. *(Fr.)* Khouri, K.; Ferneini, S.; Tabbara, W. (Hotel Dieu de France, Beirut, Lebanon). *J. Med. Liban* 26(4):407-424, 1973.

A 37-yr-old Palestinian woman whose daughter had died of Burkitt's lymphoma developed chronic diarrhea which was refractory to drug treatment. Rectal biopsy showed a nonspecific inflammatory lesion containing a cyst-like structure which may have been parasitic although stools were negative for parasites. Metronidazole and salicylazosulfapyridine caused normalization of transit time and disappearance of abdominal pain, but diarrhea recurred and a hard mass the size of an orange appeared in the right iliac fossa. Symptomatic and radiological improvement occurred and the erythrocyte sedimentation rate decreased with dehydroemetine. Further improvement occurred with ampicillin (1.5 g/day), metronidazole, and chloroquine, but the abdominal mass remained unchanged. At surgery a tumor 15 cm long was removed from the ascending colon. Histological findings were compatible with a pseudolymphomatous form of colitis. Continued improvement occurred with salicylazosulfapyridine maintenance except for epigastric cramps which developed during family difficulties. These cramps responded to antacids and anticholinergic agents. Mediterranean lymphoma was ruled out by the absence of heavy α-chains. A 33-yr-old Palestinian man with a history of dysentery dating back 4-5 yr had a painful mass to the left of the umbilicus and radiological findings compatible with a primary or invasive lymphoma in the transverse colon. Histological examination of the resected mass showed segmental ulcerative colitis and lymphoid hyperplasia with chronic lymphadenitis. Although the histories in both of these cases are suggestive of amebomas, histological findings are not consistent with this diagnosis.

2522 STUDIES OF HUMAN AMEBIASIS. III. AMEBOMA: A RADIOLOGIC MANIFESTATION OF AMEBIC COLITIS. *(E.)* Pittman, F. E.; Pittman, J. C.; El-Hashimi, W. K. (Med. Univ. South Carolina, Charleston). *Am. J. Dig. Dis.* 18(12):1025-1031, 1973.

Four patients (2 males and 2 females, aged 19-50 yr) with well-documented amebic colitis had colonic deformities suggestive of ameboma. Barium enema examination showed that each of the 4 had cecal coning and 1, an additional sigmoid lesion. Only 1 patient with a cecal lesion had a palpable, tender mass in the right lower quadrant. Indirect hemagglutination tests for amebiasis were positive in all cases. Treatment with a low-dose metronidazole regimen (250 mg, 3 times/day for 7-10 days) produced clinical and parasitologic cure in 2 cases. In 1 case a second course of metronidazole (500 mg/3 times/day for 10 days) was required for clinical cure and a third course (750 mg, 3 times/day for 10 days) for parasitologic cure. The patient presenting with the right lower quadrant mass received a second 10-day course of 750 mg metronidazole due to recurrent tenderness in this area and persistence of the cecal deformity. Subsequent physical examination failed to reveal a palpable mass. Barium enema with air contrast demonstrated more complete filling of the cecum. Marked radiologic improvement was observed in the 2 other patients available for follow-up. Since ameboma may be confused with carcinoma, a search for amebae in stool and an indirect hemagglutination test for amebiasis can prevent unnecessary and potentially disastrous surgery.

2523 MEBENDAZOLE IN ENTEROBIASIS. A PLACEBO-CONTROLLED TRIAL IN A PAEDIATRIC COMMUNITY. *(E.)* Fierlafijn, E.; Vanparijs, O. F. (Jannsen Pharmaceutica, Beerse, Belgium). *Trop. Geogr. Med.* 24(3):242-244, 1973.

Of 65 children treated with mebendazole (100 mg), 43 were positive for *Enterobius vermicularis* prior to medication, while only 4 were positive after treatment. In a group of 65 children treated with placebo, the number of positive children was 41 before and 42 after treatment. Of 40 positive children whose first medication was placebo, 39 were negative consequent to mebendazole medication. The cure rate for the drug, based on the 83 microscopically positive children, was 94%. Mebendazole was exceptionally well tolerated; no side effects were observed despite the fact that the same dosage was given to all children regardless of weight or age (2-1/2 yr to 8 yr 10 months).

2524 THE ACCIDENTAL DISCOVERY THAT SODIUM DIATRIZOATE (HYPAQUE) INFUSION WILL VISUALIZE AMEBIC ABSCESSES ON HEPATIC TOMOGRAMS. *(E.)* Chang, S.; Hildebrandt, W.; Silvis, S. E. (VA Hosp., Minneapolis, Minn.). *Am. J. Trop. Med. Hyg.* 23(1):31-34, 1974.

Two cases of successfully treated amebic liver abscess are reported in which hepatic tomograms following i.v. infusion of sodium diatrizoate visualized the walls of amebic abscesses. The first case was of a 25-yr-old male. Plain abdominal X-ray films showed a questionable irregularity of the upper pole of the right kidney and a slightly enlarged liver. Barium enema was normal. The liver scan with technetium^{99} M sulfur colloid revealed a large area of poor uptake in the right lobe. Nephrotomograms revealed a normal right kidney; but a large cystic structure in the hepatic area was seen in the 6 through 18 cm planes. The area appeared consistent with the filling defect on the liver scan. The patient was started on emetine and chloroquine, which was followed by rapid improvement of the symptoms. The second case was a 23-yr-old male. Prompt clinical response to emetine and chloroquine strongly supported the diagnosis of amebic abscess. Hepatic tomograms with i.v. infusion of sodium diatrizoate showed a round area of radiolucency in the right lobe of the liver surrounded by a narrow radiopaque band. Both the cases had had colitis in South Vietnam. The diagnosis of amebic liver abscess in the 2 cases is well established with the history of amebic colitis, abnormal hepatic scan, and the immediate responses to therapy.

2525 PENICILLAMINE AS AN ADJUVANT TO ANTIMONIAL THERAPY OF SCHISTOSOMIASIS: EFFECT ON LIVER FUNCTION TESTS IN RABBITS AND ON ANTISCHISTOSOMAL ACTIVITY. *(E.)* Khayyal, M. T.; Saleh, S.; El Masri, A. M. (Fac. Pharm., Cairo Univ., Egypt). *Bull. W.H.O.* 48(4):415-420, 1973.

The possible protective effect of penicillamine on the hepatic toxicity of antimonyl potassium tartrate was investigated in male rabbits. Tests of liver function showed changes in the level of serum aspartate and alanine aminotransferase and of alkaline phosphatase, and in the beta-/alpha-lipoprotein ratio, in response to antimony treatment. The changes were significantly reduced by penicillamine, though the effect depended on the dose. Penicillamine was found to give the best overall protection without affecting the antischistosomal efficacy of the antimonial when a 1:2 antimonyl potassium tartrate/penicillamine ratio was used. The findings provide further evidence of the potential usefulness of penicillamine in the antimonial treatment of schistosomiasis.

2526 IMMUNITY TO FASCIOLA HEPATICA IN RATS: THE EFFECT OF TWO DIFFERENT LEVELS OF PRIMARY EXPOSURE ON SUPERINFECTION. *(E.)* Hayes, T. J.; Bailer, J.; Mitrovic, M. (Hoffmann-La Roche, Inc., Nutley, N.J.). *J. Parasitol.* 59(5):810-812, 1973.

The effect of minimal infection with *F. hepatica* (1 metacercaria/rat) on a challenge infection was studied and compared with a higher level of infection (10 metacercariae/rat). Seventy-six percent fewer flukes developed from a challenge infection in rats with an existing infection of one *F. hepatica* than in rats not previously exposed. Rats first exposed to 10 metacercariae were able to resist completely a challenge exposure. Existing fluke burdens from the primary exposure were not significantly affected by challenge. The results corroborate and extend an earlier study on immunity to superinfection with *F. hepatica* in rats, and the ability of one existing fluke to cause a marked reduction from challenge is taken to indicate that nonspecific liver inflammation and damage existing at the time of challenge may not play a necessary role in immunity to *F. hepatica* in rats.

GENERAL

Regional Enteritis

548 GALLSTONES IN INFLAMMATORY BOWEL DISEASE. *(E.)* Baker, A. L.; Kaplan, M. M.; Norton, . A.; Patterson, J. F. (New England Med. Ctr. Hosp., Boston Mass.). *Am. J. Dig. Dis.* 19(2):109-112, 1974.

Chronic disease of the terminal ileum is associated with a high prevalence of gallstones. To decide whether the ileal location of the disease is responsible for this finding, we determined the prevalence of gallstones in 189 patients with all types of inflammatory bowel disease. The prevalence of gallstones in patients with disease involving the terminal ileum (regional enteritis and granulomatous ileocolitis) was 28.2% compared to a prevalence of 3.1% in patients with inflammatory bowel disease confined to the colon (ulcerative colitis and granulomatous colitis). The prevalence of gallstones in a hospital comparison population, age and sex matched to the regional enteritis-granulomatous ileocolitis group, was 11.7%. In patients with disease of the ileum, the presence of gallstones was correlated with the length of ileum involved, ileal resection, and duration of disease. The data suggest that the ileal location of the disease is of major importance. The high prevalence of gallstones found in the patients with regional enteritis and granulomatous ileocolitis, and the correlation between length of ileal involvement and gallstones, support the current concept of gallstone formation. Since the primary site for the absorption of bile salts is the terminal ileum, regional enteritis and granulomatous ileocolitis might cause a chronic loss of bile salts from the body, and in turn, a decreased cholesterol solubilizing capacity of gallbladder bile.

2549 ARTHRITIS AND CROHN'S DISEASE. A FAMILY STUDY. *(E.)* Haslock, I. (Dept. Med., Univ. Leeds, England). *Ann. Rheum. Dis.* 32(6):479-486, 1973.

A study was undertaken of the articular diseases of 116 patients with Crohn's disease and the families of 98 of them. Of the probands, 24 (20.7%), were diagnosed as having enteropathic synovitis. This was an episodic polysynovitis affecting large rather than small joints and lower limb rather than upper limb joints. The synovitis almost invariably accompanied or followed the onset of intestinal symptoms and showed a tendency to be associated with exacerbations of the disease and to be ameliorated by surgery. Radiological sacroilitis was found in 19 patients, of whom 8 (6.9%) had clinical ankylosing spondylitis. Five of these had an associated peripheral arthritis. In contrast to the enteropathic synovitis, neither the onset nor the course of the spondylitis had any relationship to the onset and course of the intestinal disease. Radiological sacroilitis was found in 8.3%, of the first-degree and 1.9% of the second-degree relatives. The articular complications of Crohn's disease are common, and are probably the commonest extraintestinal manifestation of the disease. Enteropathic synovitis appears to be a complication of active gut disease, whereas ankylosing spondylitis appears to be an hereditary accompaniment.

2550 AN EPIDEMIOLOGIC AND DEMOGRAPHIC STUDY OF INFLAMMATORY BOWEL DISEASE IN BLACK PATIENTS. *(E.)* Samuels, A. D.; Weese, J. L.; Berman, P. M.; Kirsner, J. B. (Dept. Med., Univ. Chicago, Ill.). *Am. J. Dig. Dis.* 19(2):156-160, 1974.

An analysis of inflammatory bowel disease in black people is presented and compared with a similar analysis of 1,557 patients at the University of Chicago. The diagnoses of the 58 blacks with inflammatory bowel disease included: ulcerative colitis and proctitis; regional enteritis; and ileocolitis. The most frequent age at onset of ulcerative colitis was 20 to 29 yr. The most frequent age at onset of regional enteritis was 10 to 19 yr: a secondary peak was noted in the 30-39 yr range. The most frequent age of onset of ileocolitis was 20 to 29 yr. The most frequent age at onset of granulomatous inflammation was 10 to 19 yr. The ratios of females to males are: 2:1 in regional enteritis, 1:1 in ileocolitis; and 1.56:1 for Crohn's disease. Eleven percent in the ulcerative colitis, and 30% in the Crohn's disease patients, were unskilled laborers. In ulcerative colitis, arthritic symptoms and peptic ulcers occurred at a significantly higher rate in blacks. In Crohn's disease, blacks were statistically more likely to develop fissures. Drug reactions and urinary tract infections were also more common in blacks than in the entire white project group. Blacks who present with inflammatory bowel disease are more likely to be better educated. The major manifestations of ulcerative colitis and Crohn's disease are comparable in blacks and the entire project population. The more frequent occurrence of complications of the disease among blacks is of note.

2551 STUDIES ON CROHN'S DISEASE. II. IMMUNOGLOBULIN-CONTAINING CELLS IN THE TERMINAL ILEUM. *(E.)* Persson, S.; Danielsson, D. (Regionsjukhuset, Orebro, Sweden). *Acta Chir. Scand.* 139(8):735-738, 1973.

The numbers of immunoglobulin-containing cells in the mucosa of terminal ileum were counted by a direct immunofluorescence (IFL) technique in resected tissue from 10 patients with Crohn's disease, and from 6 patients operated on for other disorders with this part of the intestine not inflamed. In the control patients, IgA-containing cells were predominant in all specimens with a ratio of IgA:IgG varying between 30.3 to 1.3 and of IgA:IgM between 9.6 to 1.7. Beside the staining of immune cells, IFL staining was also obtained of the mucus outside the epithelial cells and also in epithelial crypts. Obvious inflammatory signs were noted in sections of the terminal ileum from the patients with Crohn's disease. Immunoglobulin-containing cells located in the lamina propria were counted. The ratio of IgA:IgG varied from 0.3 to 1.6. The ratio of IgA:IgM varied from 0.7 to 9.0. The number of immunoglobulin-containing cells were considerably greater in the specimens from the patients with Crohn's disease than in the specimens from the controls. IGG- and IgA-containing cells dominated over IgM-containing cells. In a few patients, a heavy IFL staining of IgG-containing cells was observed in certain granulomas giving the impression of an active germ center. The findings in this study indicate a strong disturbance in the normal balance between the ratio of IgA: IgG-containing cells in the mucosa of the terminal ileum with Crohn's disease. The observations indicate that the IgA defense line has been broken and that the IgG-IgM system is activated in a way typical for an antigenic stimulation of non-mucosal tissue.
